Abstract

**Background:** As the population of people with CF (pwCF) continues to age, attention is shifting towards addressing the unique challenges teenagers and adults face, including substance use. Changing attitudes and legality regarding marijuana and CBD may influence their use among pwCF, but data on their prevalence, reasons for use, and administration methods are lacking. **Objective:** Investigate marijuana, cannabidiol (CBD), e-cigarette, and cigarette usage among pwCF and explore differences in demographics, disease severity, and CFTR modulator use between current and non-users. **Methods:** This cross-sectional study used a one-time electronic survey to assess marijuana, CBD, e-cigarette, and cigarette use in pwCF aged >13 years. Demographic and clinical characteristics were compared between current users and non-users. The association between current substance use and CFTR modulator use was analyzed using logistic regressions. **Results:** Among 226 participants, 29% used marijuana, 22% used CBD, 27% used e-cigarettes, and 22% used cigarettes. Current users of all substances were more likely to be college-educated, Black, or aged 29-39 years than non-users. Current e-cigarette users were 2.9 times more likely to use CFTR modulators (95% CI 0.98-11.00, p=0.08) and current marijuana users were 2.5 times more likely to use CFTR modulators compared to non-users, adjusted for confounders. Current users of CBD, e-cigarettes, and cigarettes were more likely to have an abnormal mental health screen compared to non-users. A high proportion of never-users of marijuana and CBD expressed interest in using. **Conclusion:** Substance use is more prevalent among pwCF than previously reported and needs to be addressed by healthcare providers.

Introduction

Over the past decade, there has been a notable change in the consumption patterns of inhaled and ingested substances, driven in part by the increased legalization of cannabis and the growing popularity of electronic cigarettes (e-cigarettes). While cigarette use is on the decline, the use of e-cigarettes and marijuana has witnessed an upward trend, which is expected to continue with the ongoing progress of cannabis legalization across states and diminishing societal stigma. Despite these changes, there remains limited research on the frequency of use, effectiveness, and safety of these substances for various medical conditions, particularly among individuals with underlying lung disease.

Cystic fibrosis (CF), formerly considered a fatal condition, as many individuals did not live past childhood, has experienced a remarkable transformation, largely attributed to advances in precision medicine and the introduction of modulator therapy. As the CF population continues to age, attention is shifting towards addressing unique challenges teenagers and adults face, including mental health and substance use. People with CF (pwCF) may seek complementary and alternative treatments to address common issues associated with their chronic illness, including treatment burden, anxiety, depression, decreased appetite, pain, and sleep disturbances. Moreover, as health outcomes improve in the era of effective modulator therapy and...
respiratory symptoms become less prominent, pwCF may resort to inhalation of substances that could have significant impact on their lung health.

Limited data currently exists on the prevalence, modalities, perceptions, demographic, and health factors associated with using marijuana, cannabidiol (CBD), e-cigarettes, and cigarettes in pwCF, particularly in the era of effective modulator therapy. In the past decade, there were only two studies on substance abuse in CF; both were conducted prior to the legalization of marijuana and prior to the majority of pwCF qualifying for effective modulator therapy. Given these evolving circumstances, it is essential to reexamine substance use and its perception among pwCF. Gaining a deeper understanding of substance usage patterns can enhance the quality of clinical care and provide valuable insights into the underlying reasons, empowering healthcare teams to provide informed guidance and support.

In this study, we investigated the prevalence of marijuana, CBD, e-cigarette, and cigarette usage within the CF community and the characteristics of users. We sought to determine if pwCF using these substances were on CFTR modulators as well. Lastly, we investigated reasons for and attitudes regarding substance usage and self-reported clinical outcomes with substance use.

Methods

Study Design

This was a cross-sectional study using a one-time electronic survey about the use of marijuana, CBD, e-cigarettes, and cigarettes among pwCF.

Study recruitment took place from January to May 2022 using various online platforms, including closed membership CF support groups on Facebook, newsletters from the CF Foundation, and CF centers via the CF listserv. The survey was administered through web-based REDcap surveys available in English.

Subjects

Subjects were included if they were 13 years and older, diagnosed with CF, and residing in the United States.

Substance Use Terminology

Subjects were asked about the substances used, including marijuana, CBD, e-cigarettes, or cigarettes defined in a consistent manner below:

- **Marijuana and CBD products**: The cannabis plant contains more than 120 chemical compounds, including delta-9-tetrahydrocannabinol (THC) and CBD. THC is psychoactive and is responsible for the intoxicating effects commonly associated with marijuana use. CBD is a non-psychoactive compound that has gained popularity for its potential therapeutic effects, including reducing inflammation, pain, and anxiety. Marijuana has THC levels greater than 0.3% and varied levels of CBD. Marijuana included any form, including but not limited to edibles, tinctures, oil, and joints. CBD products have low levels of THC (less than 0.3%) and higher levels of CBD. CBD includes any form, including but not limited to gummies, creams, oils, and pills.
- **E-cigarettes/Vaping**: E-cigarettes are electronic battery-powered devices containing a liquid that is vaporized and inhaled. It can be referred to as vape pen, hookah-pens, electronic hookahs (e-hookahs), electronic cigars (e-cigars), electronic pipes (e-pipes), or e-vaporizers.
- **Cigarettes**: Cigarettes are rolls of finely cut tobacco leaves wrapped in paper that is smoked.

Measures

Substance use frequency: **Current users** were classified as those who reported using marijuana, CBD, e-cigarettes, or cigarettes within the past 12 months and did not report quitting. Current uses were asked about frequency of use (daily or almost daily, at least once a week, at least once a month, or less than monthly), reasons for using, and side effects experienced. **Former users** were those who reported previous use of marijuana, CBD, e-cigarettes, or cigarettes but not in the past 12 months. Former users were asked about reasons for quitting. **Never users** were those who never used marijuana, CBD, e-cigarettes, or cigarettes.
Never users were asked about their attitudes towards the substance and interest in using them in the future. The non-user group includes both former users and never users.

**Substance use modality:** Current substance users were asked what modality they used overall and more often. Marijuana modalities included smoking (in a joint, bong, pipe, blunt), eating (in brownies, cakes, cookies, candy), drinking (in tea, cola, alcohol), vaporizing (in e-cigarette-like vaporizer), dabbing (using butane hash oil, wax, concentrates), or some other modality. CBD modalities included sublingual, capsules or pills, mouth spray, topical, vaping, smoking, suppository, edibles, drinking, or using some other modality. E-cigarettes are a modality but can contain different mists, including nicotine, marijuana, CBD, only flavoring, or other liquid.

**Reasons for Use and Side Effects:** For each substance, current substance users were asked the reason for use, such as anxiety, fun, appetite stimulant, peer group use. Current users reported if they use marijuana for medical, recreational, or both reasons. For each substance, current users reported any positive or negative effects experienced. For each side effect or symptom experienced, subjects rated the severity from much worse to much better. Subjects reported if they experienced weight or lung function changes with use.

**Attitudes towards substances:** Never users were given three statements for each substance, including "I would never use no matter what", "I am willing to learn more about the potential benefits and risks", "I am curious about using but have not had the opportunity", and an additional statement specifically for marijuana "I am open to using it if it were legalized". They provided their ratings on a sliding scale, ranging from 0-10, which were grouped into five categories ranging from strongly disagree to strongly agree.

**CF Disease Characteristics:** Subjects reported their pancreatic enzyme use, latest forced expiratory volume in one second (FEV₁) percent predicted (greater than 80%, between 70-79%, between 60-69%, below 60%, other, I’m not sure), perceived overall health (poor, fair, good, very good, excellent), and perceived lung health (poor, fair, good, very good, excellent). Subjects were asked if they were currently on a CFTR modulator.

**Demographics :** Subject demographics included self-identified: age, race/ethnicity (Asian or Pacific Islander, Black or African American, Hispanic or Latino, Native American or Alaskan Native, White or Caucasian, A race or ethnicity not listed here, prefer not to answer), gender (female, male, transgender, non-binary, prefer to self-describe, prefer not to answer) state of residence, highest education level achieved (college degree or higher, no college degree) and household income (unsure/not making an income, less than $50,000, $50,000-$99,999, more than $100,000).

**Mental health:** Subjects’ mental health was assessed utilizing the patient health questionnaire 4 (PHQ-4), which consists of two anxiety and two depression questions. Total score >3 on either the anxiety or depression questions indicated positivity for either of those disorders and was considered an abnormal mental health screen. Scores are rated as normal (0-2), mild (3-5), moderate (6-8), and severe (9-12)

The survey consisted of four sections of questions on each substance (marijuana, cannabidiol, e-cigarettes, and cigarettes), with a total of 110 questions. The survey also included a section which asked subjects about their experiences with their healthcare team. The survey was comprised of branching logic and skip questions. Subjects who reported not using any substance received a minimum of 30 questions to answer. The format of the survey included multiple choice, Likert scale ratings, slider questions, and open-ended questions. The survey was reviewed, and feedback was given by the CF Foundation.

**Statistical analysis**

Survey responses were tabulated and reported as counts and percentages. Current users were compared to non-current users of each substance for all analyses. To assess differences in socioeconomic characteristics, demographics, and illness severity markers, Fisher’s exact test was used. Univariate and multivariate logistic regressions were performed to evaluate the unadjusted and adjusted association between usage of CFTR modulators and current usage of each substance. Potential confounders included in the multivariate models were chosen a priori based on prior literature and a directed acyclic graph of the framework.
of potential relationships of use of CFTR modulators and substance use. Potential confounders were gen-
ner (female, male, other), age (13-25, 26-39, 40-80 years old), race and ethnicity (non-Hispanic White, 
Asian/Black/Hispanic/other race), FEV\textsubscript{1} percent predicted (<60, 60-79, >80%), PHQ-4 (normal/mild, 
moderate/severe). Subjects with missing data were excluded from the regression analyses. A p-value of less 
than 0.05 was considered statistically significant. All statistical analyses were conducted using R version 
4.2.1 (R Foundation for Statistical Computing, Vienna, Austria). The study procedures were reviewed and 
approved by the Institutional Review Board at the University of California, San Francisco (21-34926).

**Results**

Of the 226 subjects with CF who completed the one-time survey and met inclusion criteria, current use 
was reported by 29% \( (n=66) \) of subjects for marijuana, 22% \( (n=49) \) for CBD, 27% \( (n=60) \) for e-cigarettes, 
and 22% \( (n=49) \) for cigarettes. Only 0.9% \( (n=2) \) subjects used all four substances, 6.2% \( (n=14) \) used three 
substances, and 22.6% \( (n=51) \) used two of the substances currently (Figure 1).

The frequency of marijuana, CBD, e-cigarette, and cigarette usage varied among those who reported current 
use. Daily or near-daily use was highest in users of cigarette (45%, \( n=22 \)) and e-cigarette (33%, \( n=20 \)). 
Marijuana users were more likely to use daily or near-daily (23%, \( n=15 \)) compared to CBD users (16%, 
\( n=8 \)). A total of 30% \( (n=26) \) of marijuana users, 33% \( (n=16) \) CBD, and 35% \( (n=21) \) e-cigarette users had 
at least once a week usage compared to 22% \( (n=11) \) of cigarette users (Figure 2).

Overall, we found that current users of each of the four substances were more likely to be college-educated, 
between the ages of 26 and 39 years old, and Black when compared to non-users. Demographic and socioe-
conomic characteristics between current users and non-users differ depending on the substance used (Table 
1). Compared to non-users, current users of CBD, e-cigarettes, and cigarettes were more likely to be male, 
which contrasts with current marijuana users, who were slightly more likely to identify as female and other 
gender identities. Black subjects were more likely to be current users of all substances than other races. 
Non-Hispanic white subjects were more likely to be current users of marijuana and cigarettes. Asian, Native 
American, other races, or multi-race subjects were more likely to be current users of e-cigarettes. Specific 
to marijuana, there was no significant association between current marijuana usage and state of residence 
in terms of legality (illegal, medically legal, legalized).

Significant patterns also emerged with respect to markers of CF disease severity and PHQ-4 scores between 
current users and non-users (Table 2). Current marijuana users were more likely to be on pancreatic enzymes, 
while current cigarette users were less likely to be on pancreatic enzymes. Subjects with self-reported FEV\textsubscript{1} 
percent predicted of 60-80% were more likely to be current users of e-cigarettes and cigarettes as compared 
to non-users who were more likely to have a self-reported FEV\textsubscript{1} less than 60% and greater than 80%. There 
were no differences in pulmonary function between current users and non-users of marijuana or CBD.

Current users of CBD, e-cigarettes, and cigarettes were more likely to have an abnormal mental health screen 
by PHQ-4 compared to non-users. CBD users were more likely than non-users to have a severe score on 
the PHQ-4, report depressive symptoms on the PHQ-4, but there was no difference in anxiety symptoms. 
E-cigarette and cigarette users were more likely to have a mild, moderate, and severe score on the PHQ-4 
than non-users, as well as, more likely to report anxiety and depressive symptoms on the PHQ-4. There was 
no significant difference found in mental health between users and non-users of marijuana.

There were differences in CFTR modulator use between current-users and non-users of substances. Current 
marijuana users were 1.92 times more likely to report being on CFTR modulators in univariate logistic 
regression (95% CI 0.87-4.70, \( p=0.1 \)) and 2.45 times more likely in the multivariate logistic model adjusted 
for age, gender, race, ethnicity, ppFEV\textsubscript{1}, and PHQ-4 (95% CI 0.97-7.17, \( p=0.08 \)). Current users of e-
cigarettes were 4.07 times more likely to report taking CFTR modulators (95% CI 1.54-14.07, \( p=0.01 \)) in 
the univariate logistic regression, and 2.92 times more likely in the multivariate analysis adjusted for age, 
gender, race, ethnicity, ppFEV\textsubscript{1}, and PHQ-4 (95% CI 0.98-11.00, \( p=0.08 \)). Although the differences for 
both marijuana and e-cigarettes did not reach statistical significance, the confidence intervals exclude any 
meaningful differences of lower CFTR modulator use in current substance users compared to non-users.
There were no significant differences in current cigarette or CBD users by CFTR modulator use in logistic regressions (Table 3).

**Reasons for Use**

The reasons for use varied across substances, with a common theme of anxiety and social influences (such as friends and family) emerging among the top reasons for use across all four substances. Among marijuana users, sleep disturbance was the most common reason for use, while among CBD users, pain management was the most common reason for use. E-cigarettes were primarily used for flavor experimentation and curiosity, while reasons for cigarette use were stress relief and enjoyment (Table 4). Specific to marijuana, 30% (n=20) of subjects used it for medical reasons, 27% (n=18) for recreational, and 42% (n=28) used it for both.

**Effects of Substance Use:**

Substance users reported various effects, some positive and some negative (Table xx). Both marijuana and CBD users reported concentration difficulties and energy changes; CBD users mainly noted an improvement in energy, while marijuana users noted increased drowsiness. Appetite changes were frequently reported; many marijuana users reported improved appetite, while many e-cigarette and cigarette users reported decreased appetite. E-cigarette users frequently experience nausea and vomiting. Cough and shortness of breath were often reported by e-cigarette and cigarette users. Despite reporting various effects of substance use, the majority of current users reported no weight or lung function changes related to their substance use.

**Quitting Substance Use:**

The rates of quitting and the reasons for quitting varied between substances. Former users of marijuana and CBD were more likely to quit than former users of e-cigarettes and cigarettes. Surprisingly, 33% (n=32) formerly used marijuana and 38% (n=30) formerly used CBD, while only 12% (n=8) formerly used e-cigarettes and 22% (n=14) formerly used cigarettes. There were a wide variety of reasons reported for quitting each substance. Among former marijuana users, the primary motivations for quitting were lack of enjoyment (58%, n=14) and a desire to avoid getting high (50%, n=12). While the primary reason cited by former CBD users for quitting was the perception of ineffectiveness (43%, n=13). Health concerns were cited as the predominant factors for quitting among e-cigarette (75%, n=6) and cigarette (71%, n=10) users.

**Never-users**

Many subjects reported never experimenting with any substances, with 56.6% (n=128) having never tried marijuana, 65.0% (n=147) having never tried CBD, 69.9% (n=158) having never tried e-cigarettes, 72.1% (n=163) having never tried cigarettes and 38.5% (n=87) having never tried any of these four substances in their lifetime.

Attitudes varied among those who had never used substances. Subjects who have never used marijuana or CBD displayed less aversion to these substances than those who have never used e-cigarettes or cigarettes. Among never-users, a higher proportion of participants agreed with the statement, “I would never use no matter what” in relation to e-cigarettes (77%, n=122) and cigarettes (81%, n=132) compared to marijuana (30%, n=39) and CBD (26%, n=38). Many non-users were curious about using marijuana and CBD; 48% (n=61) of never-users of marijuana and 60% (n=88) of never-users of CBD agreed with the statement, “I am curious about using but have not had the opportunity”. In comparison, only a small percentage of never-users of e-cigarettes (8%, n=12) and cigarettes (5%, n=8) agreed with that statement. Many never-users of marijuana (65%, n=83) and CBD 60%, n=88) agreed with the statement, “I do not know enough about this substance, but I am open to learning more about the risks and benefits”. In contrast, very few never-users of e-cigarettes (5%, n=8) and cigarettes (3%, n=5) agreed with this statement. More than half of marijuana never-users were interested in trying marijuana if it was legal (52%, n=67).

**Discussion**

In this cross-sectional study of marijuana, CBD, e-cigarette, and cigarette use in teenagers and adults with CF, we found that a substantial proportion of pwCF engaged in experimentation with at least one of these substances. The reasons for use varied across substances, with a common theme of anxiety and social influences (such as friends and family) emerging among the top reasons for use across all four substances. Among marijuana users, sleep disturbance was the most common reason for use, while among CBD users, pain management was the most common reason for use. E-cigarettes were primarily used for flavor experimentation and curiosity, while reasons for cigarette use were stress relief and enjoyment. Specific to marijuana, 30% (n=20) of subjects used it for medical reasons, 27% (n=18) for recreational, and 42% (n=28) used it for both. Substance users reported various effects, some positive and some negative. Both marijuana and CBD users reported concentration difficulties and energy changes; CBD users mainly noted an improvement in energy, while marijuana users noted increased drowsiness. Appetite changes were frequently reported; many marijuana users reported improved appetite, while many e-cigarette and cigarette users reported decreased appetite. E-cigarette users frequently experience nausea and vomiting. Cough and shortness of breath were often reported by e-cigarette and cigarette users. Despite reporting various effects of substance use, the majority of current users reported no weight or lung function changes related to their substance use.

The rates of quitting and the reasons for quitting varied between substances. Former users of marijuana and CBD were more likely to quit than former users of e-cigarettes and cigarettes. Surprisingly, 33% (n=32) formerly used marijuana and 38% (n=30) formerly used CBD, while only 12% (n=8) formerly used e-cigarettes and 22% (n=14) formerly used cigarettes. There were a wide variety of reasons reported for quitting each substance. Among former marijuana users, the primary motivations for quitting were lack of enjoyment (58%, n=14) and a desire to avoid getting high (50%, n=12). While the primary reason cited by former CBD users for quitting was the perception of ineffectiveness (43%, n=13). Health concerns were cited as the predominant factors for quitting among e-cigarette (75%, n=6) and cigarette (71%, n=10) users. Many subjects reported never experimenting with any substances, with 56.6% (n=128) having never tried marijuana, 65.0% (n=147) having never tried CBD, 69.9% (n=158) having never tried e-cigarettes, 72.1% (n=163) having never tried cigarettes and 38.5% (n=87) having never tried any of these four substances in their lifetime.

Attitudes varied among those who had never used substances. Subjects who have never used marijuana or CBD displayed less aversion to these substances than those who have never used e-cigarettes or cigarettes. Among never-users, a higher proportion of participants agreed with the statement, “I would never use no matter what” in relation to e-cigarettes (77%, n=122) and cigarettes (81%, n=132) compared to marijuana (30%, n=39) and CBD (26%, n=38). Many non-users were curious about using marijuana and CBD; 48% (n=61) of never-users of marijuana and 60% (n=88) of never-users of CBD agreed with the statement, “I am curious about using but have not had the opportunity”. In comparison, only a small percentage of never-users of e-cigarettes (8%, n=12) and cigarettes (5%, n=8) agreed with that statement. Many never-users of marijuana (65%, n=83) and CBD 60%, n=88) agreed with the statement, “I do not know enough about this substance, but I am open to learning more about the risks and benefits”. In contrast, very few never-users of e-cigarettes (5%, n=8) and cigarettes (3%, n=5) agreed with this statement. More than half of marijuana never-users were interested in trying marijuana if it was legal (52%, n=67).

In this cross-sectional study of marijuana, CBD, e-cigarette, and cigarette use in teenagers and adults with CF, we found that a substantial proportion of pwCF engaged in experimentation with at least one of these substances and often reported various effects, some positive and some negative.
substances over their lifetime. Surprisingly, approximately one-quarter (xx%) of subjects surveyed reported currently using either marijuana, CBD, e-cigarettes, or cigarettes, with marijuana and e-cigarettes being the most commonly used substance.

We found notable differences in the prevalence of marijuana, e-cigarette, and cigarette usage in pwCF compared to prior studies. Our study reports the prevalence of CBD usage in pwCF for the first time, showing a prevalence of 22% (n=49). In a cross-sectional study of teenagers and young adults with CF, Hamberger and colleagues found that 27.4% (n=51) of subjects used marijuana, 15.2% (n=51) used e-cigarettes and 25.7% (n=87) used cigarettes in their lifetime. However, their study did not investigate current usage. In our study, we found a much higher prevalence of lifetime use of marijuana (43.4%), e-cigarettes (30.1%), and cigarettes (27.9%). We also found a higher prevalence of current users than other studies with 29.4% (n=66) of subjects reporting marijuana use in the last year. In contrast, a cross-sectional study of six CF centers found a lower prevalence, with 16.5% reporting marijuana use in their lifetime and 15.4% in the last year. This study by Stephen and colleagues focused on usage and attitudes towards medical marijuana in pwCF, while our study focused on all use of marijuana in pwCF. The higher prevalence of marijuana usage likely reflected the changing legalization of marijuana in the United States in recent years. The higher prevalence of usage of the other substances in our study also reflected broader trends in substance use in the United States; our data is consistent with national data from the general U.S. population, showing that 43% of Americans used marijuana, 19% vaped nicotine, 22% vaped marijuana, and 19% used cigarettes in the last year.

Characteristics of Substance Users

Our study gathered important information about characteristics of pwCF who use substances that have not been previously reported. Substance use was higher across all substances among pwCF who were college-educated, aged 26 to 39 years old, or Black. While male pwCF were more likely to be current users of CBD, e-cigarettes, and cigarettes, pwCF who are female or have other gender identities were more likely to use marijuana currently. Interestingly, current use of e-cigarettes and cigarettes were less likely to have severe or normal lung function compared to non-users; Current use of e-cigarettes and cigarettes was the higher in those with mild or moderate lung disease. There was no significant difference in pulmonary function by usage of marijuana and CBD. Our hypothesis to explain these findings is that individuals with poorer lung function may have increased healthcare interactions therefore a heightened understanding of vaping risks, while those with better lung function may exhibit higher health awareness. It is important to note that while our study identified important demographic and health characteristics associated with various substance use in pwCF, the prevalence of substance use overall was high in our study. Our findings confirmed the importance of incorporating substance use discussions and education into routine care regardless of demographic, health, or socioeconomic status.

Substance Modalities

We observed a high prevalence of marijuana vaporization and smoking, and a surprisingly high utilization of inhalational methods for CBD. CBD is often less frequently asked about among CF healthcare teams, and many CF care providers feel unprepared to answer questions regarding CBD. Given the potential for worsening lung disease and respiratory symptoms, it is vital to routinely discuss both marijuana and CBD usage, counsel, and discuss modalities. Inhaling any substance can exacerbate airway inflammation and hasten lung damage, especially in those already afflicted with underlying lung disease. Furthermore, alternative forms of marijuana and CBD, such as edibles and topical solutions, present challenges due to their higher cost, limited accessibility, and potential interactions with CFTR modulator drugs, thereby potentially complicating their usage as an alternative to CF management strategies.

CFTR Modulators and Substance Use

With significant improvements in lung and overall health with highly effective modulator therapy, we investigated the prevalence of substance use in pwCF on CFTR modulators. We found that e-cigarette and marijuana use were more than two times higher in those on CFTR modulators than those not on CFTR
modulators. Although these associations did not reach statistical significance after adjusting for other factors, these associations are likely clinically meaningful as there was a strongly positive trend of the odds ratio, and essentially rule out that pwCF on CFTR modulators have lower substance use. There were no significant differences in CBD and cigarette use between those on and not on CFTR modulators. The increased trend in e-cigarette and marijuana use among those on CFTR modulators poses significant concerns as there is ample data on lung injuries associated with e-cigarettes\textsuperscript{14}. Tobacco smoke exposure can cause impairment in CFTR functional expression, which may mitigate the benefit of CFTR modulators\textsuperscript{14}. The impact of marijuana smoke exposure on CFTR expression has not been studied. With social influence and increased access to these agents, it is critical that drug use assessment and education be implemented in routine CF care, especially as pwCF live longer in the era of effective modulator therapy to prevent adverse outcomes from substance use.

### Untreated symptoms

Mental health continues to be a major concern in pwCF\textsuperscript{16,17}. In our study, many subjects had abnormal mental health screens; except for marijuana, poor mental health was associated with current substance use. Notably, current e-cigarette and cigarette users were associated with anxiety and depression, while current CBD users were associated with depressive symptoms. Many reported using substances to minimize the impact of their illness and improve their mental well-being, often to address anxiety, depression, and sleep issues. Current users frequently stated using CBD and marijuana as mood stabilizers; however, hyperawareness and anxiety were also reported as side effects. Approximately half of the subjects who quit marijuana reported wanting to avoid psychoactive effects. Although current users noted worsening mental health with e-cigarettes and cigarettes and a desire to stop using, quitting rates were lower when compared to marijuana and CBD, likely due to the highly addictive nature of nicotine\textsuperscript{18}. While the causal relationship between substance use and mental health remains uncertain, it is crucial to recognize that some substances can exacerbate pre-existing mental health issues frequently observed in patients with chronic diseases\textsuperscript{19}. It is also worth noting that some patients may experience neurocognitive, mood, and anxiety changes after initiating CFTR modulator therapy. Our study did not explore the relationship between modulator therapy initiation, substance use timing and mood which may be a confounding factor.

### Risk for increased use in CF population

Similar to findings reported by Stephen and colleagues\textsuperscript{6}, we also found that approximately half of the subjects who had never used would try marijuana or CBD if given the opportunity or if marijuana was legal. This indicates a probable increase in substance usage among the CF community as societal stigma around marijuana decreases and legality continues to shift. In addition, we found that many pwCF used substances due to the influence of friends and family and seeking a sense of normalcy, as seen in a prior study\textsuperscript{20}. As pwCF are leading longer lives with fewer significant health disruptions due to CFTR modulators, substance use prevalence may increase over time.

There is a great need to expand the current knowledge of and guidance regarding marijuana and CBD use in the CF patient population. Further research is warranted to counsel pwCF accurately, as many report experiencing therapeutic benefits. With the advancements in therapies that enhance the quality of life and increase life expectancy, coupled with evolving legal landscapes, pwCF will have more opportunities to explore these substances than previous generations.

In this study, we have identified several factors with respect to substance use in pwCF that merit further consideration in CF routine patient care and future research. Most importantly, CF care providers must screen for substance use starting in the patient’s early teenage years. Second, CF care providers should feel comfortable addressing the topics of marijuana, CBD, e-cigarettes, and cigarette use and potential risks with patients and families. Finally, more studies are needed to understand potential interactions between these substances, especially marijuana and CBD and the concomitant use of CFTR modulators.

### Study Limitations:

...
There are a few notable limitations to our study. First, we relied on self-reported rather than clinical data, so the associations of substance use with health outcomes and CFTR modulators may be under- or over-reported. Second, the survey was administered through online channels utilizing social media platforms, a method susceptible to infiltration of fraudulent responses. We addressed this by including internal validity questions and using CAPTCHA (Completely Automated Public Turing test to tell Computers and Humans Apart) feature. We carefully reviewed the validity questions and removed suspected automated responses by bots from the study. Third, subjects recruited via social media may represent pwCF who have an interest in these substances, which would potentially overestimate the prevalence, however, we found that the prevalence was not significantly skewed toward current use relative to non-use. The survey was also not translated into Spanish, limiting the participation of a subset of potential subjects, and our findings' generalizability; therefore, our results should not preclude discussions around substance use in all pwCF.

Conclusion:

Our study demonstrated an increased trend for all substance uses in pwCF. As e-cigarettes become more popular and more states legalize marijuana for medical and recreational use, it will become crucial to establish consistent guidelines, screening tools, and enhanced research efforts to understand potential health risks and benefits specific to this population. CF healthcare teams should routinely counsel their patients regarding substance use.

Acknowledgments: We thank all the people with CF who participated in this study
