Slit lamp images with direct illumination (a and b) and retroillumination (c). A 64-year-old woman with history of phacoemulsification and single-piece intraocular lens (IOL) placement had an extracapsular anterior dislocation of the IOL four years ago. The dislocated IOL was subsequently removed out of the capsular bag and a new three-piece IOL was placed in the posterior chamber with scleral fixation. Three months later, an unexpected total migration of the empty capsular bag into the anterior chamber was observed. The slit lamp images also show ghost traces of the previous IOL haptic.
