Abstract

Wu and Verdú developed a theory of almost lossless analog compression, where one imposes various regularity conditions on the compressor and the decompressor with the input signal being modelled by a (typically infinite-entropy) stationary stochastic process. In this work we consider all stationary stochastic processes with trajectories in a prescribed set of (bi-)infinite sequences and find uniform lower and upper bounds for certain compression rates in terms of metric mean dimension and mean box dimension. An essential tool is the recent Lindenstrauss-Tsukamoto variational principle expressing metric mean dimension in terms of rate-distortion functions. We obtain also lower bounds on compression rates for a fixed stationary process in terms of the rate-distortion dimension rates and study several examples.
METRIC MEAN DIMENSION AND ANALOG COMPRESSION

YONATAN GUTMAN AND ADAM SPIEWAK

Abstract. Wu and Verdú developed a theory of almost lossless analog compression, where one imposes various regularity conditions on the compressor and the decompressor with the input signal being modelled by a (typically infinite-entropy) stationary stochastic process. In this work we consider all stationary stochastic processes with trajectories in a prescribed set of (bi-)infinite sequences and find uniform lower and upper bounds for certain compression rates in terms of metric mean dimension and mean box dimension. An essential tool is the recent Lindenstrauss-Tsukamoto variational principle expressing metric mean dimension in terms of rate-distortion functions. We obtain also lower bounds on compression rates for a fixed stationary process in terms of the rate-distortion dimension rates and study several examples.

I. Introduction

I.A. Overview. In recent years, the theory of compression for analog sources (modeled by real-valued stochastic processes) underwent a major development (as a sample of such results see [2], [3], [4], [5], [6], [7], [8], [9]). There are two key differences with the classical Shannon’s model of compression for discrete sources. The first one is the necessity to employ regularity conditions on the compressor and/or decompressor functions (e.g. linearity or Lipschitz/Hölder continuity). This requirement makes the problem both non-trivial (since highly irregular bijections between $\mathbb{R}$ and $\mathbb{R}^n$ cannot be applied to obtain arbitrary small compression rates) and reasonable from the point of view of applications (since it induces robustness to noise). The second difference is the fact that non-discrete sources have in general infinite Shannon entropy rate, hence a different measure of complexity for stochastic processes must be considered. One of the most fruitful approaches taken in the literature is to assume a specific structure of the source signal. Apparently the most prominent instance of such an approach is the theory of compressed sensing, where the input vectors are assumed to be sparse. 1 In this setting, the theory of linear compression with efficient and stable recovery algorithms has been developed. However, strong assumptions posed on the structure of the signal reduce the applicability of the technique. A different approach was developed in the pioneering work of Wu and Verdú [2]. Instead of making assumptions on the structure of the signal, new measures of complexity related to the box-counting (Minkowski) dimension of the signal were introduced and proved to be bounds on the compression rates for certain classes of compressors and decompressors. Jalali and Poor ([4], [5]) developed the theory of universal compressed sensing for stochastic processes with $\psi^*$-mixing property, where the compression and decompression algorithms do not require an a priori knowledge of the source distribution. The corresponding compression rates are given in terms of a certain generalization of the Rényi information dimension. Compression algorithms for general stationary processes (assuming an a priori knowledge of process dependent compression codes) were obtained in [6].

The goal of this paper is twofold. We adapt the setting from [2], but instead of a single process we consider all stationary stochastic processes with trajectories in a prescribed set $\mathcal{S} \subset [0,1]^2$ of

1 cf. [10], [11], [12]. For a comprehensive treatment on compressed sensing see [13]. For applications in sampling theory see [14]. For similar results in the more general case of signals from unions of linear subspaces see [15] and [16].
is natural to assume the set $S$ of dynamical systems to the study of compression rates. As we consider stationary processes, it is our main tool in developing lower bounds on compression rates for all of the quantization of a stochastic process at a given scale (for more details see [28]).

This rate-distortion functions - objects well studied in information theory, describing the entropy rate recently in [27], where a variational principle for metric mean dimension was given in terms of Lindenstrauss (cf. [25], see also [26]). Another connection between these domains was established recently in [24], where the use of sampling theorems was an essential tool for proving the embedding conjecture of Lindenstrauss (cf. [25], see also [26]).

Considerations on the connections between signal processing and metric mean dimension theory was observed first in [24], where the use of sampling theorems was an essential tool for proving the embedding conjecture of Lindenstrauss (cf. [25], see also [26]). Another connection between these domains was established recently in [27], where a variational principle for metric mean dimension was given in terms of rate-distortion functions - objects well studied in information theory, describing the entropy rate of the quantization of a stochastic process at a given scale (for more details see [28]).

This variational principle is our main tool in developing lower bounds on compression rates for all

We focus on two compression schemes: with Borel or linear compressors and Hölder (Lipschitz) decompressors. Such or similar schemes were considered in the literature in the case of a single stochastic process (e.g. [2, 5, 6, 8]). Except for considering an ensemble of processes instead of a single one, there are two main differences in our approach with respect to [2]. We consider processes with trajectories in $[0,1]^2$, hence we assume a uniform bound on the attained values. We also demand decompressor functions to fulfill $(L,\alpha)$-Hölder condition with fixed $L > 0$ and $\alpha \in (0,1]$ for all block lengths. In particular, the Lipschitz constant $L$ has to be uniformly bounded for arbitrary long codes. This novelty guarantees improved robustness to noise. Our results are upper and lower bounds for such rates in terms of certain dynamical-geometric characteristics of the considered set $S$. The main result is a lower bound on the worst-case compression rate for Borel compression and $(L,\alpha)$-Hölder decompression in terms of the metric mean dimension of the set $S$. We illustrate this fundamental limit by several examples, including parametrized family of sparse signal subshifts, where we show that our fundamental bound turns out to be tight (in the asymptotic range $L \to \infty$). Admitting general Borel compressors makes this result applicable to a wide class of compression schemes (e.g. both linear and ones involving quantization). This result is accompanied by two upper bounds (achievability results). The first one is an upper bound in the context of Borel compression and $(L,\alpha)$-Hölder decompression. It is obtained by employing constructions akin to the Peano space-filling curve of Hölder surjective maps between unit cubes. This type of construction would not be possible for more stringent regularity requirements for the decompressor. The second upper bound is a zero-probability error bound for linear compression with $(L,\alpha)$-Hölder decompression. It is given in terms of the mean box dimension of the set $S$ and it is deduced from a finite-dimensional embedding theorem involving the upper box-counting (Minkowski) dimension (see [22]).

We obtain also lower bounds on compression rates for a fixed stationary process in terms of the rate-distortion dimension (see [6]; see also [9] for a more detailed treatment on the connections between various notions of dimension for stochastic processes).

The fact that above bounds are obtained in terms of the metric mean dimension and mean box dimension of the set $S$ realizes the second goal of the paper: introducing notions from the theory of dynamical systems to the study of compression rates. As we consider stationary processes, it is natural to assume the set $S$ to be invariant under the shift transformation and hence it can be considered as a topological dynamical system. Metric mean dimension is a geometrical invariant of dynamical systems introduced and studied by Lindenstrauss and Weiss in [23]. Existence of connections between signal processing and mean dimension theory was observed first in [24], where the use of sampling theorems was an essential tool for proving the embedding conjecture of Lindenstrauss (cf. [25], see also [26]). Another connection between these domains was established recently in [27], where a variational principle for metric mean dimension was given in terms of rate-distortion functions - objects well studied in information theory, describing the entropy rate of the quantization of a stochastic process at a given scale (for more details see [28]). This variational principle is our main tool in developing lower bounds on compression rates for all
stationary processes supported in $S$. Mean box dimension is a box-counting dimension version of the projective dimension introduced by Gromov in [29]. The results of this paper can be also seen as an attempt to provide operational meaning for metric mean dimension in stochastic terms (in the sense that it gives fundamental limits for the corresponding compression problem), hence they contribute to the program of relating ergodic theory to the theory of mean dimension initiated in [24].

I.B. Organization of the paper. In Section II we introduce basic notions and notations. In Section III we define analog compression rates (following [2]). In Section IV we introduce geometric and dynamical notions of dimension (box-counting dimension, metric mean dimension and mean box dimension) and illustrate them by basic examples. In Section V we state the main results of the paper. In Section VI we present several examples, which serve as illustrations to the main results. Section VII contains the variational principle for metric mean dimension in the case of subshifts, which is our main tool in developing lower bounds on certain compression rates. Section VIII discusses related works by other authors. Section IX contains proofs of the main results. Section X contains concluding remarks. In the Appendices we give more details on metric mean dimension theory from the perspective of dynamical systems, prove several auxiliary results and present calculations for examples from Sections IV and VI.

II. Notation

By $\mathbb{N} = \{1, 2, \ldots\}$ we will denote the set of natural numbers, by $\mathbb{N}_0 = \{0, 1, 2, \ldots\}$ the set of natural numbers with zero and by $\mathbb{Z}$ the set of integers. We take the base of the logarithm to be equal to 2. For a (finite or infinite) vector $x = (x_n)$ and $\ell \leq k$ we denote $x|_{\ell}^k = (x_\ell, \ldots, x_k)$. By $\#A$ we will denote the cardinality of the set $A$.

In this paper, we apply results from the theory of dynamical systems to the theory of signal processing. From the signal processing perspective, we will consider stationary stochastic process $\{X_n : \Omega \to [0,1] \mid n \in \mathbb{Z}\}$ defined on some probability space $(\Omega, \mathbb{P})$. Usually, instead of a single process, we will be interested in considering all the stationary processes with trajectories in some prescribed set $S$.

A useful description of this setting can be given in terms of dynamical systems and we will usually take this perspective. By a \textbf{(topological) dynamical system} we will understand a triple $(\mathcal{X}, T, \rho)$, where $(\mathcal{X}, \rho)$ is a compact metric space with metric $\rho$ and $T : \mathcal{X} \to \mathcal{X}$ is a homeomorphism. Many notions which we consider (e.g. metric mean dimension) are metric dependent, hence we do not suppress $\rho$ from the notation. For a (countably-additive) Borel measure $\mu$ on $\mathcal{X}$, by $T_\star \mu$ we will denote its push-forward by $T$, i.e. a Borel measure on $\mathcal{X}$ given by $T_\star \mu(A) = \mu(T^{-1}(A))$ for Borel $A \subset \mathcal{X}$. We will say that measure $\mu$ is $T$-\textbf{invariant}, if $T_\star \mu = \mu$. By $\mathcal{P}_T(\mathcal{X})$ we will denote the set of all Borel probability measures on $\mathcal{X}$ and by $\mathcal{P}_T(\mathcal{X})$ the set of all $T$-invariant Borel probability measures on $\mathcal{X}$. For a Borel measure $\mu$ on $\mathcal{X}$ its \textbf{support} is the closed set $\text{supp}(\mu) = \{x \in \mathcal{X} : \mu(U) > 0 \text{ for all open neighbourhoods } U \text{ of } x\}$. This is the smallest closed set of full measure $\mu$.

For an introduction to topological dynamics and its connections with ergodic theory see [30, Chapters 5-8].

Formally, the connection between signal processing and dynamical systems is given by considering a special class of systems: subshifts with shift transformation. Assume that $(A, d)$ is a compact metric space, which we will treat as the alphabet space. We will focus on the case $A \subset [0,1]$ with the standard metric. $A^\mathbb{Z}$ is itself a compact metrizable space when endowed with the product topology. This topology is metrizable by the product metric

$$\rho(x, y) = \sum_{i \in \mathbb{Z}} \frac{d(x_i, y_i)}{2^{|i|}},$$

where $x = (x_i)_{i \in \mathbb{Z}}$, $y = (y_i)_{i \in \mathbb{Z}}$. Note that $\text{diam}(A^\mathbb{Z}, \rho) = 3\text{diam}(A, d)$. Define the \textbf{shift transformation} $\sigma : A^\mathbb{Z} \to A^\mathbb{Z}$ as

$$\sigma((x_i)_{i \in \mathbb{Z}}) = (x_{i+1})_{i \in \mathbb{Z}}.$$

We will be interested in the properties of a given \textbf{subshift}, i.e. a closed (in the product topology) and shift-invariant subset $S \subset A^\mathbb{Z}$, which we will interpret as the set of all admissible signals that
can occur in the input and treat as a dynamical system with transformation $\sigma$. For $n \in \mathbb{N}$ denote by $\pi_n : S \to A^n$ the projection $\pi_n(x) = x|_0^{n-1}$, $x = (x_i)_{i \in \mathbb{Z}} \in S$. We will endow $[0, 1]^\mathbb{Z}$ with a product metric as in (1), i.e.

$$\tau(x, y) = \sum_{i=-\infty}^{\infty} \frac{1}{2^{|i|}} |x_i - y_i|.$$ (2)

Throughout the paper, the letter $\tau$ will always denote this specific metric. It metrizes the product topology on $[0, 1]^\mathbb{Z}$. Note that $\text{diam}(\tau) = 3$. This choice of the metric may seem arbitrary, but it turns out that metric mean dimension for subshifts takes a natural form when calculated with respect to $\tau$ (see Proposition A.3). We will consider mainly subshifts $S \subseteq [0, 1]^\mathbb{Z}$, i.e. shift-invariant subsets of $[0, 1]^\mathbb{Z}$ which are closed in the topology given by the metric $\tau$. In this language, for a given subshift $S \subseteq [0, 1]^\mathbb{Z}$, the set $\mathcal{P}_\sigma(S)$ consists of all distributions of stationary stochastic processes taking values in a given subshift $S$ (i.e. distributions of stationary stochastic processes $X_n, n \in \mathbb{Z}$ such that $(X_n)_{n \in \mathbb{Z}} \in S$ with probability one). For vectors $x, y \in [0, 1]^n, x = (x_0, \ldots, x_{n-1}), y = (y_0, \ldots, y_{n-1})$ and $p \in [1, \infty)$ we define the (normalized) $p$-th **distance** (coming from the $p$-th norm):

$$\|x - y\|_p = \left(\frac{1}{n} \sum_{k=0}^{n-1} |x_k - y_k|^p\right)^{\frac{1}{p}}$$

and

$$\|x - y\|_\infty = \max\{|x_k - y_k| : 1 \leq k \leq n\}.$$ The following inequalities hold on $[0, 1]^n$ for $1 \leq p \leq q < \infty$ (see [31, Chapter 3 - Exercise 5]):

$$\| \cdot \|_p \leq \| \cdot \|_q \leq \| \cdot \|_\infty$$

and

$$\| \cdot \|_\infty \leq n^{\frac{1}{p}} \| \cdot \|_p.$$ Note also that $\text{diam}([0, 1]^n, \| \cdot \|_p) = 1$ for every $n \in \mathbb{N}$, $p \in [1, \infty)$. For $x \in [0, 1]^n$ we will denote $\text{supp}(x) = \{0 \leq i < n : x_i \neq 0\}$ and $\|x\|_0 = \#\text{supp}(x)$. Let $\nu$ be a Borel measure on $[0, 1]$. We denote the product measure induced by $\nu$ on $[0, 1]^\mathbb{Z}$ as $\bigotimes_{\mathbb{Z}} \nu$. It corresponds distributions of memoryless (i.i.d) sources.

A sequence $\mathbb{N} \ni n \mapsto a_n \in [0, \infty)$ is called **subadditive** if $a_{n+k} \leq a_n + a_k$ for every $n, k \in \mathbb{N}$. We will apply several times the following well-known fact (see e.g. [32, Propostion 6.2.3]): if $n \mapsto a_n$ is a subadditive sequence, the limit $\lim_{n \to \infty} \frac{a_n}{n}$ exists and equals $\inf_{n \in \mathbb{N}} \frac{a_n}{n}$.

**Remark II.1.** In the paper [2], Wu and Verdú consider processes taking values in the space $\mathbb{R}^N$, whereas we will consider the space $[0, 1]^\mathbb{Z}$. From the formal point of view, this assumption is made in order to obtain compactness of the considered space. From the point of view of applications, this corresponds to an a priori bound on signals (up to rescaling). We also consider two-sided sequences instead of one-sided - this corresponds to having an access to the past of the state of the system and makes the acting transformation $\sigma$ invertible, which is a useful assumption in dynamical systems. However, all notions under consideration depend only on the future and the corresponding results remain unchanged in the non-invertible case.

### III. Analog compression rates

In this section we introduce analog compression rates for sources with non-discrete alphabet. They measure the rate at which a given signal can be compressed assuming certain restrictions on the performance and regularity of the compression-decompression process. The definitions are analogous to the achievable rates as defined in [2, Definition 5]. We consider subshifts in $[0, 1]^\mathbb{Z}$ and invariant measures supported in them. In this setting it is natural to assume further constraints on the compressor and decompressor functions. This follows from the fact that the alphabet $[0, 1]$ is infinite: there exists an injection from any $A \subseteq [0, 1]^n$ into $[0, 1]$. Therefore, if we do not assume any regularity of the compressor or decompressor functions, the asymptotic compression rate is always $0$. This is also true if we allow only Borel compressors and decompressors (see [2, Section IV-B]). On the other hand, from the point of view of applications it is also desirable to assume some regularity conditions on the compressor and decompressor functions, since they induce robustness
to noise and enable numerical control of the errors occurring in the compression and decompression processes (e.g. by requiring encoders and decoders to be Hölder).

III.A. Definitions of compression rates. We will introduce now several regularity classes which will be used throughout the paper.

**Definition III.A.1.** A regularity class with respect to the norm \( \| \cdot \|_p, p \in [1, \infty] \) is a set \( C \) of functions between finite dimensional unit cubes, i.e. \( C \subset \{ f : [0, 1]^n \to [0, 1]^k : n, k \in \mathbb{N} \} \). We will consider the following regularity classes:

1. **Borel** \( \mathcal{B} = \{ f : [0, 1]^n \to [0, 1]^k \mid n, k \in \mathbb{N}, f \text{ is Borel} \} \)

2. **\( L \)–Lipschitz for \( L > 0 \)**

\[ L^p_L = \{ f : [0, 1]^n \to [0, 1]^k \mid n, k \in \mathbb{N}, \| f(x) - f(y)\|_p \leq L\| x - y\|_p \text{ for all } x, y \in [0, 1]^n \} \]

3. **Lipschitz**

\[ \mathcal{L} = \{ f : [0, 1]^n \to [0, 1]^k \mid n, k \in \mathbb{N}, \exists L > 0 \| f(x) - f(y)\|_p \leq L\| x - y\|_p \text{ for all } x, y \in [0, 1]^n \} \]

4. **(\( L, \alpha \))-Hölder for \( \alpha \in (0, 1] \)**

\[ \mathcal{H}_{p,p}^{L,\alpha} = \{ f : [0, 1]^n \to [0, 1]^k \mid n, k \in \mathbb{N}, \| f(x) - f(y)\|_p \leq L\| x - y\|^{\alpha}_p \text{ for all } x, y \in [0, 1]^n \} \]

5. **\( \alpha \)-Hölder for \( \alpha \in (0, 1] \)**

\[ \mathcal{H}_\alpha = \{ f : [0, 1]^n \to [0, 1]^k \mid n, k \in \mathbb{N}, \exists \exists L > 0 \| f(x) - f(y)\|_p \leq L\| x - y\|^{\alpha}_p \text{ for all } x, y \in [0, 1]^n \} \]

6. **Hölder**

\[ \mathcal{H} = \{ f : [0, 1]^n \to [0, 1]^k \mid n, k \in \mathbb{N}, \exists \exists \exists \exists L > 0 \| f(x) - f(y)\|_p \leq L\| x - y\|^{\alpha}_p \text{ for all } x, y \in [0, 1]^n \} \]

7. **Linear**

\[ \text{LIN} = \{ f : [0, 1]^n \to [0, 1]^k \mid n, k \in \mathbb{N}, \exists \exists \exists \exists F : \mathbb{R}^n \to \mathbb{R}^k \text{ is linear and } f = F|_{[0,1]^n} \} \]

**Remark III.A.2.** Note that we omit \( p \) in the notation for classes \( \mathcal{B} \) and LIN, as they clearly do not depend on the choice of the norm. Classes \( \mathcal{H}, \mathcal{H}_\alpha \) and \( \mathcal{L} \) are also independent of \( p_i \) as all norms on a finite-dimensional real vector space are equivalent, yet note that the Lipschitz constant of a given map in any of these classes may depend on the choice of the norm.

**Remark III.A.3.** Notice that the identity map \( \text{id} : [0, 1]^n \to [0, 1]^n \) belongs to all of the above classes, except for \( \mathcal{L}_L \) and \( \mathcal{H}_L^{p,p} \). Indeed for those two classes, we have \( \text{id} \in \mathcal{L}_L, \mathcal{H}_L^{p,p} \) if and only if \( L \geq 1 \).

Let us define now three compression rates that we will study throughout the paper.

**Definition III.A.4.** (See [2, Definition 3]) Let \( \mu \in \mathcal{P}_\sigma([0, 1]^Z) \). Let \( \mathcal{C}, \mathcal{D} \subset \{ f : [0, 1]^n \to [0, 1]^k : n, k \in \mathbb{N} \} \) be regularity classes. For \( n \in \mathbb{N} \) and \( \varepsilon \geq 0 \), the \( \mathcal{C} - \mathcal{D} \) almost lossless analog compression rate \( r_{\mathcal{C} - \mathcal{D}}(\mu, \varepsilon, n) \geq 0 \) of \( \mu \) with \( n \)-block error probability \( \varepsilon \) is the infimum of

\[ \frac{k}{n}, \]

where \( k \) runs over all natural numbers such that there exist maps

\[ f : [0, 1]^n \to [0, 1]^k, \ f \in \mathcal{C} \ \text{and} \ \ g : [0, 1]^k \to [0, 1]^n, \ g \in \mathcal{D} \]

with

\[ \mu(\{ x \in [0, 1]^Z \mid g \circ f(x)_{[0, n-1]} \neq x_{[0, n-1]} \}) \leq \varepsilon. \]

Define further:

\[ r_{\mathcal{C} - \mathcal{D}}(\mu, \varepsilon) = \limsup_{n \to \infty} r_{\mathcal{C} - \mathcal{D}}(\mu, \varepsilon, n). \]

In the next definition, we fix a subshift \( \mathcal{S} \subset [0, 1]^Z \) and consider compressors and decompressors providing almost lossless compression for all measures \( \mu \in \mathcal{P}_\sigma(\mathcal{S}) \). In such a case, compression can be performed without knowledge of the distribution from which the signal comes, as long as the process is supported in \( \mathcal{S} \).
Definition III.A.5. Let $S \subset [0,1]^2$ be a subshift. Let $\mathcal{C}, \mathcal{D} \subset \{f : [0,1]^n \to [0,1]^k : n,k \in \mathbb{N}\}$ be regularity classes. For $n \in \mathbb{N}$ and $\varepsilon \geq 0$, the $\mathcal{C} - \mathcal{D}$ uniform almost lossless analog compression rate $r_{\mathcal{C} - \mathcal{D}}(S, \varepsilon, n) \geq 0$ of $S$ with $n$-block error probability $\varepsilon$ is the infimum of
\[ \frac{k}{n}, \]
where $k$ runs over all natural numbers such that there exist maps
\[ f : [0,1]^n \to [0,1]^k, \ f \in \mathcal{C} \quad \text{and} \quad g : [0,1]^k \to [0,1]^n, \ g \in \mathcal{D} \]
such that
\[ \mu(\{x \in S \mid g \circ f(x)^{n-1} \neq x^{|n-1}\}) \leq \varepsilon \]
holds for all $\mu \in \mathcal{P}_\sigma(S)$.

Define further:
\[ r_{\mathcal{C} - \mathcal{D}}(S, \varepsilon, n) = \limsup_{n \to \infty} r_{\mathcal{C} - \mathcal{D}}(S, \varepsilon, n). \]

We introduce also an $L^p$ variant.

Definition III.A.6. Let $\mu \in \mathcal{P}_\sigma([0,1]^2)$. Let $\mathcal{C}, \mathcal{D} \subset \{f : [0,1]^n \to [0,1]^k : n,k \in \mathbb{N}\}$ be regularity classes with respect to the norm $\| \cdot \|_p$. For $n \in \mathbb{N}$, $\varepsilon \geq 0$ and $p \in [1,\infty)$, the $\mathcal{C} - \mathcal{D}$ $L^p$-analog compression rate $r_{\mathcal{C} - \mathcal{D}}^{L^p}(\mu, \varepsilon, n) \geq 0$ of $\mu$ with $n$-block mean error $\varepsilon$ is the infimum of
\[ \frac{k}{n}, \]
where $k$ runs over all natural numbers such that there exist maps
\[ f : [0,1]^n \to [0,1]^k, \ f \in \mathcal{C} \quad \text{and} \quad g : [0,1]^k \to [0,1]^n, \ g \in \mathcal{D} \]
with
\[ \int_{[0,1]^n} \| x - g \circ f(x) \|_p^p d(\pi_n)_\ast \mu(x) \leq \varepsilon^p. \]

Define further:
\[ r_{\mathcal{C} - \mathcal{D}}^{L^p}(\mu, \varepsilon, n) = \limsup_{n \to \infty} r_{\mathcal{C} - \mathcal{D}}^{L^p}(\mu, \varepsilon, n). \]

Note that in this work we will consider the $L^p$-compression rate for regularity classes with respect to the matching norm $\| \cdot \|_p$.

Remark III.A.7. All of the above compression rates are non-increasing in $\varepsilon$, i.e. if $\varepsilon \leq \varepsilon'$ then $r(\mu, \varepsilon, n) \geq r(\mu, \varepsilon', n)$ and $r(\mu, \varepsilon) \geq r(\mu, \varepsilon')$. Let $\mathcal{C}, \mathcal{D}$ be regularity classes such that $id_{[0,1]^n} \in \mathcal{C}, \mathcal{D}$ for every $n \in \mathbb{N}$. Then $r(\mu, \varepsilon) \leq 1$ holds for all $\mu \in \mathcal{P}_\sigma(S)$ and $\varepsilon \geq 0$. If $\mathcal{C}$ and $\mathcal{D}$ are regularity classes with respect to a norm such that $\text{diam}([0,1]^n, \| \cdot \|) = 1$ for every $n \in \mathbb{N}$ (note that we normalize norms $\| \cdot \|_p$, $p \in [1,\infty]$ such that this holds), then
\[ r_{\mathcal{C} - \mathcal{D}}^{L^p}(\mu, \varepsilon) \leq r_{\mathcal{C} - \mathcal{D}}(\mu, \varepsilon^p). \]
for $1 \leq p < \infty$ and $\mu \in \mathcal{P}_\sigma(S)$.

Remark III.A.8. One could have used a seemingly more permissive definition with the compressor function defined only on a set of words of length $n$ occurring in $S$, i.e. with conditions
\[ f : \pi_n(S) \subset [0,1]^n \to [0,1]^k, \ f \in \mathcal{C} \quad \text{and} \quad g : f(\pi_n(S)) \subset [0,1]^k \to [0,1]^n, \ g \in \mathcal{D}. \]
However, if one can apply suitable extension theorems to extend functions $f, g$ to the full cubes $[0,1]^n$ and $[0,1]^k$, respectively, while maintaining assumed regularity, then this would have resulted with an equivalent definition. All of the classes in Definition III.A.1 other than LIN admit such an extension when considered with respect to the $\| \cdot \|_\infty$ norm. In particular, for classes $\mathcal{H}^{\infty}_{L,\alpha}$ this follows from Banach’s theorem on extension of Hölder and Lipschitz functions, stating that a real-valued function defined on a subset $A$ of a metric space and satisfying $|f(x) - f(y)| \leq Ld(x,y)^\alpha$ for all $x, y \in A$, can be extended to the whole metric space so as to satisfy the same inequality
([33, Theorem IV.7.5], see also [34]). Therefore, given a function \( f : A \to [0,1]^k \), \( A \subset [0,1]^n \), \( f = (f_1, \ldots, f_k) \) satisfying \( \| f(x) - f(y) \|_\infty \leq L \| x - y \|_\infty \) on \( A \), one can apply Banach’s theorem to coordinate functions \( f_1, \ldots, f_k \) (clearly satisfying \( |f_j(x) - f_j(y)| \leq L \| x - y \|_\infty \)), obtaining extensions \( \tilde{f}_1, \ldots, \tilde{f}_k : [0,1]^n \to \mathbb{R} \). Then \( \tilde{f}_1, \ldots, \tilde{f}_k : [0,1]^n \to [0,1] \) given as \( \tilde{f}_j(x) = \max \{ \min \{ f(x), 1 \} , 0 \} \) are again \((L,\alpha)\)-Hölder and satisfy \( \tilde{f}_j = f_j \) on \( A \). Therefore \( \tilde{f} = (\tilde{f}_1, \ldots, \tilde{f}_k) \) is an extension of \( f \) from \( A \) to \([0,1]^n\) and

\[
\| \tilde{f}(x) - \tilde{f}(y) \|_\infty = \max_{1 \leq j \leq k} \| \tilde{f}_j(x) - \tilde{f}_j(y) \|_\leq L \| x - y \|_\infty.
\]

This yields an extension theorem for \( \mathcal{H}^\infty_{L,\alpha} \). By [34, Theorem 1], analogous result is true for the class \( \mathcal{H}^p_{L,\alpha} \). The above considerations apply also to \( \mathcal{H}^p_{L,\alpha} \) for other \( p \in [1, \infty) \), however the extended function might have a worse Lipschitz constant \( L \). Namely, repeating the above argument for a function \( f : A \to [0,1]^k \) satisfying \( \| f(x) - f(y) \|_p \leq L \| x - y \|_A \), the coordinate functions \( f_j \) will satisfy \( |f_j(x) - f_j(y)| \leq k^\frac{1}{p} \| f(x) - f(y) \|_p \leq k^\frac{1}{p} L \| x - y \|_p \). Therefore, the extended function \( \tilde{f} \) is guaranteed to satisfy

\[
\| f(x) - f(y) \|_p \leq k^\frac{1}{p} L \| x - y \|_p.
\]

In other words, \((L,\alpha)\)-Hölder function in the norm \( \| \cdot \|_p \) can be extended to an element of \( \mathcal{H}^p_{k^\frac{1}{p} L,\alpha} \).

It is known that in general one cannot have an extension theorem for Hölder maps preserving the Lipschitz constant for \( p \in (1, \infty) \setminus \{2\} \) (see [35, Section 1.30]). In conclusion, if \( C,D \in \{B, L, N, \mathcal{H}_A, \mathcal{H}^\infty_{L,\alpha}, \mathcal{H}^2_{L,\alpha}\} \), then (4) will result in equivalent definitions of compression rates.

### IV. Mean dimensions

In this section we will introduce two dynamical notions of mean dimensions: metric mean dimension and mean box dimension. They attempt to capture the average number of dimensions per time unit required to describe a given system and can serve as complexity measures of a subshift. The main results of this paper are certain bounds on compression rates in terms of these mean dimensions.

#### IV.A. Box dimension

Let us begin by introducing the non-dynamical notion of box-counting dimension. It will serve a basis for dynamical definitions of mean dimensions.

**Definition IV.A.1.** Let \((X, \rho)\) be a compact metric space. For \( \varepsilon > 0 \), the \( \varepsilon \)-covering number of a subset \( A \subset X \), denoted by \(#(A, \rho, \varepsilon)\), is the minimal cardinality \( N \) of an open cover \( \{ U_1, \ldots, U_N \} \) of \( A \) such that all \( U_n \) have diameter smaller than \( \varepsilon \). The \( \varepsilon \)-net in \( A \) is a subset \( E \subset A \) such that for every \( x \in A \) the distance \( d(x, E) := \inf_{y \in E} \rho(x, y) \) is strictly smaller than \( \varepsilon \).

Note that in \( A \) there exists an \( \varepsilon \)-net of cardinality \(#(A, \rho, \varepsilon)\). When the metric \( \rho \) is coming from a norm \( \| \cdot \| \) (i.e. \( \rho(x, y) = \| x - y \| \)), we will write simply \(#(A, \| \cdot \|, \varepsilon)\) for \(#(A, \rho, \varepsilon)\).

**Definition IV.A.2.** Let \((X, \rho)\) be a compact metric space. The upper box-counting (Minkowski) dimension of \( A \subset X \) is defined as

\[
\overline{\dim}_B(A) = \limsup_{\varepsilon \to 0} \frac{\log #(A, \rho, \varepsilon)}{\log \frac{1}{\varepsilon}}.
\]

Similarly the lower box-counting dimension of \( A \) is defined as

\[
\underline{\dim}_B(A) = \liminf_{\varepsilon \to 0} \frac{\log #(A, \rho, \varepsilon)}{\log \frac{1}{\varepsilon}}.
\]

If upper and lower limits coincide, then we call its common value the box-counting dimension of \( A \) and denote it by \( \dim_B(A) \).

In the sequel we will consider primarily sets \( A \subset [0,1]^n \) with the distance induced by the norm \( \| \cdot \|_\infty \). Note that, any other equivalent metric on \([0,1]^n \) (e.g. \( \| \cdot \|_p \), \( p \in [1, \infty) \)) will give the same values of box-counting dimensions. Some of the basic properties of box-counting dimensions are summarized in the next proposition (see e.g. [36, Prop. 3.3 and 3.4]).

**Proposition IV.A.3.** Let \( A, B \) be subsets of compact metric spaces. Then
(1) if \( A \subset B \), then \( \overline{\dim}_B(A) \leq \overline{\dim}_B(B) \) and \( \dim_B(A) \leq \dim_B(B) \)
(2) \( \overline{\dim}_B(A \cup B) \leq \max\{\overline{\dim}_B(A), \overline{\dim}_B(B)\} \)
(3) \( \overline{\dim}_B(A \times B) \leq \overline{\dim}_B(A) + \overline{\dim}_B(B) \)
(4) \( \overline{\dim}_B([0,1]^n) = n \)

For more on the dimension theory see [37], [38] and [36].

IV.B. Metric mean dimension and mean box dimension. The notion that we will be mostly interested in is the metric mean dimension:

**Definition IV.B.1.** Let \( S \subset [0,1]^\mathbb{Z} \) be a subshift. The upper and lower metric mean dimensions of the system \( S \) are defined as

\[
\overline{\text{mdim}}_M(S) = \limsup_{\varepsilon \to 0} \lim_{n \to \infty} \frac{\log \#(\pi_n(S), \| \cdot \|_\infty, \varepsilon)}{n \log \frac{1}{\varepsilon}}
\]

and

\[
\underline{\text{mdim}}_M(S) = \liminf_{\varepsilon \to 0} \lim_{n \to \infty} \frac{\log \#(\pi_n(S), \| \cdot \|_\infty, \varepsilon)}{n \log \frac{1}{\varepsilon}}.
\]

The study of mean dimension type invariants in dynamical systems goes back to Gromov [29]. The notion of metric mean dimension was introduced by Lindenstrauss and Weiss in [23]. The above formula is valid for subshifts in \([0,1]^\mathbb{Z}\), however metric mean dimension was originally defined by a different (but equivalent) formula, which applies to any dynamical system on a compact metric space (see Proposition A.3). In Appendix A we present the general definition, the proof of equivalence and more remarks on metric mean dimension from the point of view of dynamical systems. We will consider one more notion of mean dimension. It is a box-counting dimension version of the projective dimension introduced by Gromov in [29].

**Definition IV.B.2.** For a subshift \( S \subset [0,1]^\mathbb{Z} \) we define its upper mean box dimension as

\[
\overline{\text{mdim}}_B(S) = \lim_{n \to \infty} \overline{\text{dim}}_B(\pi_n(S)),
\]

where \( \overline{\text{dim}}_B(\pi_n(S)) \) is calculated with respect to any \( \| \cdot \|_p \) norm on \([0,1]^n\) (the limit exists as the sequence \( n \to \overline{\text{dim}}_B(\pi_n(S)) \) is subadditive, since \( \pi_{n+k}(S) \subset \pi_n(S) \times \pi_k(S) \)).

Note that \( \overline{\text{mdim}}_B(S) \) is defined as \( \overline{\text{mdim}}_M(S) \), but with exchanged order of limits. They fulfill the following inequality, which is an analog of Gromov’s pro-mean inequality [29, Subsection 1.9.1].

**Proposition IV.B.3.** Let \( S \subset [0,1]^\mathbb{Z} \) be a subshift. Then

\[
\underline{\text{mdim}}_M(S) \leq \overline{\text{mdim}}_B(S).
\]

For the proof see Appendix B.

IV.C. Examples. Let us present now several examples (with some of the calculations postponed to Appendix E).

**Example IV.C.1.** Let \( A \subset [0,1] \) be a closed subset. Then \( S = A^\mathbb{Z} \subset [0,1]^\mathbb{Z} \) is a subshift satisfying

\[
\underline{\text{mdim}}_M(S) = \overline{\text{mdim}}_B(S) = \overline{\text{dim}}_B(A).
\]

By Proposition IV.B.3 it is enough to prove

\[
\overline{\text{dim}}_B(A) \leq \underline{\text{mdim}}_M(S) \quad \text{and} \quad \overline{\text{mdim}}_B(S) \leq \overline{\text{dim}}_B(A)
\]

The lower bound follows from [39, Thm. 5]. For the upper bound note that \( \pi_n(S) = A^n \), hence by Proposition IV.A.3.3, \( \overline{\text{dim}}_B(\pi_n(S)) = \overline{\text{dim}}_B(A^n) \leq \underline{\text{mdim}}_B(A) \).

In general, equality does not hold in Proposition IV.B.3.
Example IV.C.2. For $m \geq 1$ let

$$A_m := \{(\ldots, 0, 0)\} \times [0, \frac{1}{2m}]^m \times \{(0, 0, \ldots)\} \subset [0, 1]^\mathbb{Z},$$

where the cube $[0, \frac{1}{2m}]^m$ is located on coordinates $0, 1, \ldots, m - 1$. Set

$$S_m = \bigcup_{n \in \mathbb{Z}} \sigma^n(A_m) \text{ and } S := \bigcup_{m \geq 1} S_m.$$

Then $S$ is a subshift satisfying

$$\text{mdim}_M(S) = 0 \text{ and } \overline{\text{mdim}}_B(S) = 1.$$

For calculations see Appendix E.A.

Let us now consider an example which arises naturally in the context of compressed sensing for sparse signals. It will be our main example throughout the paper.

Example IV.C.3. Fix $K, N \in \mathbb{N}$ with $K \leq N$. Let $S \subset [0, 1]^\mathbb{Z}$ be the subshift consisting of $(N, K)$-sparse vectors, i.e.

$$S = \{x \in [0, 1]^\mathbb{Z} : \forall j \in \mathbb{Z}, \|x\|_{j+N-1} \leq K\}.$$

We will call $S$ the $(N, K)$-sparse subshift. It satisfies

$$\text{mdim}_M(S) = \overline{\text{mdim}}_B(S) = \frac{K}{N}.$$

Let us prove these equalities. By Proposition IV.B.3, it is enough to prove

$$\frac{K}{N} \leq \text{mdim}_M(S) \text{ and } \overline{\text{mdim}}_B(S) \leq \frac{K}{N}.$$

For the upper bound, observe that $\pi_{\ell N}(S)$ for $\ell \in \mathbb{N}$ is a finite union of sets of the upper box-counting dimension at most $\ell K$ (as every $x \in \pi_{\ell N}(S)$ satisfies $\|x\|_0 \leq \ell K$). Consequently, by Proposition IV.A.3.2, $\overline{\dim}_B(\pi_{\ell N}(S)) \leq \ell K$, hence $\overline{\dim}_B(S) \leq \frac{K}{N}$. For the lower bound, note that $\pi_{\ell N}(S)$ contains the set $A_\ell := ([0, 1]^K \times \{0\}^{N-K})^\ell$. For fixed $\varepsilon > 0$ we have therefore (see e.g. [37, Section 2.2])

$$\#(\pi_{\ell N}(S), \|\cdot\|_\infty, \varepsilon) \geq \#(A_\ell, \|\cdot\|_\infty, \varepsilon) \geq \left(\frac{1}{\varepsilon}\right)^{K\ell},$$

hence

$$\text{mdim}_M(S) = \liminf_{\varepsilon \to 0} \lim_{\ell \to \infty} \frac{\log \#(\pi_{\ell N}(S), \|\cdot\|_\infty, \varepsilon)}{\ell N \log \frac{1}{\varepsilon}} \geq \liminf_{\varepsilon \to 0} \lim_{\ell \to \infty} \frac{\ell K \log \frac{1}{\varepsilon}}{\ell N \log \frac{1}{\varepsilon}} = \frac{K}{N}.$$

\[\blacksquare\]

V. MAIN RESULTS

In this section we present the main results of the paper. Instead of assuming specific properties for the measure governing the source, we consider the setting in which the set of all possible trajectories is known and we look for compression rates corresponding to the worst-case scenario. Therefore the following question is our main question:

**Main Question:** Given a subshift $S \subset [0, 1]^\mathbb{Z}$, calculate

$$\sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_a(S)} r_{C-D}(\mu, \varepsilon), \quad \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_a(S)} r_{C-D}^p(\mu, \varepsilon), \quad \sup_{\varepsilon > 0} r_{C-D}(S, \varepsilon) \text{ and } r_{C-D}(S, 0)$$

for fixed regularity classes $C$ and $D$.

The above suprema correspond to rates which can be achieved whenever geometric information on the signal is given (i.e. $S$ is known), but its statistics are unknown (i.e. the particular $\mu \in S$ which governs the source is not known) and can be a priori given by any stationary distribution supported in $S$. 

9
We will be mainly interested in this question for $\mathcal{C} \in \{\mathcal{B}, \text{LIN}\}$ and $\mathcal{D} = \mathcal{H}_{L,\alpha}^p$. Such or similar regularity conditions have appeared previously in the literature (e.g. in [2, 5, 6]. See Section VIII for a more detailed discussion). Our goal is to connect the above uniform compression rates with geometric-dynamical invariants of the given subshift $\mathcal{S}$ - its mean dimensions.

Remark V.1. Note that for any compression variant it holds
\[ \sup_{\mu \in \mathcal{P}_s(\mathcal{S})} \sup_{\varepsilon > 0} r_{C - \mathcal{D}}(\mu, \varepsilon) = \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_s(\mathcal{S})} r_{C - \mathcal{D}}(\mu, \varepsilon) = \lim_{\varepsilon \to 0} \sup_{\mu \in \mathcal{P}_s(\mathcal{S})} r_{C - \mathcal{D}}(\mu, \varepsilon) = \lim_{\varepsilon \to 0} \sup_{\mu \in \mathcal{P}_s(\mathcal{S})} \inf_{\varepsilon > 0} r_{C - \mathcal{D}}(\mu, \varepsilon). \]

Below we formulate the main results of the paper. For their proofs see Section IX.

V.A. Lower bounds. Our main result is a worst-case fundamental limit on $\sup_{\varepsilon > 0} r_{B - \mathcal{H}_{L,\alpha}^p}(\mu, \varepsilon)$ and therefore on $\sup_{\varepsilon > 0} r_{B - \mathcal{H}_{L,\alpha}^p}(\mu, \varepsilon)$ and $\mathcal{P}_\sigma(\mathcal{S})$ in terms of the metric mean dimension of $\mathcal{S}$. This corresponds to the setting where the distribution of the signal is not known, but the set $\mathcal{S}$ of all possible trajectories is known (i.e. one has knowledge of the words that can occur in the input, but not their probabilities) and one is interested in the worst (largest) compression rate which is required to code the signal.

Theorem V.A.1. Let $\mathcal{S} \subset [0,1]^Z$ be a subshift. The following holds for every $0 < \alpha \leq 1, L > 0$ and $p \in [1, \infty)$:
\[ \alpha \text{mdim}_M(\mathcal{S}) \leq \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_s(\mathcal{S})} r_{B - \mathcal{H}_{L,\alpha}^p}(\mu, \varepsilon) \leq \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_s(\mathcal{S})} r_{B - \mathcal{H}_{L,\alpha}^p}(\mu, \varepsilon). \]
Similarly for $p = \infty$
\[ \alpha \text{mdim}_M(\mathcal{S}) \leq \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_s(\mathcal{S})} r_{B - \mathcal{H}_{L,\alpha}^p}(\mu, \varepsilon). \]

Intuitively, this result states that for a given set of trajectories $\mathcal{S}$, we can always find a stationary stochastic process supported in $\mathcal{S}$, which cannot be compressed at a better rate than $\alpha \text{mdim}_M(\mathcal{S})$. Note that we work with Borel compressors, which allows very general compression schemes (e.g. non-continuous quantizations) for which this bound can be applied. We consider Hölder decompressors with both Hölder exponent $\alpha$ and Lipschitz constant $L$ fixed, i.e. decompressors have to fulfill $(L, \alpha)$-Hölder condition for every blocklength (hence uniform control of the decompression error is guaranteed for arbitrary long messages). We consider compressors and decompressors as functions on finite-dimensional unit cubes, hence the Lipschitz constant of the decompressor cannot be arbitrary reduced as this necessitates expanding the image of the compressor to beyond the unit cube - this makes the above constraint non-trivial. As shown by examples in the next section, fixing $L$ (i.e. choosing $\mathcal{D} = \mathcal{H}_{L,\alpha}^p$ instead of $\mathcal{D} = \mathcal{H}_{\alpha}$) is necessary for the above bound to hold (see Example VI.A.2). It is not sharp in general (see Example VI.A.1), yet equality holds for some subshifts after letting $L \to \infty$ (we prove it for $(N, K)$-sparse subshifts in Example VI.B.1). Such equality, whenever holds, can be seen as an operational characterization of the metric mean dimension. For the proof of Theorem V.A.1 see Section IX.A.

We obtain also a lower bound on $r_{B - \mathcal{H}_{L,\alpha}^p}(\mu, \varepsilon)$ for fixed $\mu \in \mathcal{P}_\sigma(\mathcal{S})$ and $\varepsilon > 0$ (see Theorem IX.A.1) and on $r_{B - \mathcal{H}_{L,\alpha}^p}(\mu, \varepsilon)$ for fixed $\mu \in \mathcal{P}_\sigma(\mathcal{S})$ in terms of the rate-distortion dimension of a measure (see Corollary IX.A.2 for details).

V.B. Upper bounds. The lower bound of Theorem V.A.1 is accompanied by two upper bounds. The first one, concerning linear compressors and $(L, \alpha)$-Hölder decompressors, gives an upper bound on the worst-case compression rate for zero-probability error in terms of mean box dimension. It is an application of the finite-dimensional linear embedding theorem with Hölder inverse.

Theorem V.B.1. Let $\mathcal{S} \subset [0,1]^Z$ be a subshift. Then, for every $0 < \alpha < 1$ and $p \in [1, \infty]$
\[ \inf_{L > 0} r_{\text{LIN-}\mathcal{H}_{L,\alpha}^p}(\mathcal{S}, 0) \leq \frac{2}{1 - \alpha} \text{mdim}_B(\mathcal{S}). \]
By the definition of $r_{\mathrm{LIN}-\mathcal{H}^p_{L,\alpha}}(S, 0)$, the sequence of coders and decoders which achieves the above upper bound is independent of $\mu \in \mathcal{P}_\sigma(S)$, hence compression for a given distribution $\mu \in \mathcal{P}_\sigma(S)$ can be performed without prior knowledge of $\mu$, as long as $\mu$ is supported in $S$. The infimum over $L$ means that we can obtain compression rates arbitrary close to $\frac{2}{1-\alpha} \overline{\dim}_B(S)$ from above, at the cost of increasing $L$ (which, once fixed, is valid for all blocklengths). Since $r_{\mathrm{LIN}-\mathcal{H}^p_{L,\alpha}}(S, 0) \leq 1$ for $L \geq 1$ (as identity belongs to both classes LIN and $\mathcal{H}^p_{L,\alpha}$), we always have $\min\{1, \frac{2}{1-\alpha} \overline{\dim}_B(S)\}$ as the upper bound. For that reason, Theorem V.B.1 gives a meaningful bound as long as $\overline{\dim}_B(S) < \frac{1}{1-\alpha}$. Combining Theorems V.A.1 and V.B.1 we obtain the following corollary:

**Corollary V.B.2.** Let $S \subset [0,1]^Z$ be a subshift. For every $0 < \alpha < 1$ and $p \in [1, \infty)$ the following holds:

$$\alpha \overline{\dim}_M(S) \leq \inf_{L > 0} \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_\sigma(S)} r_{\mathcal{B}-\mathcal{H}^p_{L,\alpha}}(\mu, \varepsilon) \leq \inf_{L > 0} \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_\sigma(S)} r_{\mathcal{B}-\mathcal{H}^p_{L,\alpha}}(\mu, \varepsilon) \leq \inf_{L > 0} \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_\sigma(S)} r_{\mathrm{LIN}-\mathcal{H}^p_{L,\alpha}}(\mu, \varepsilon) \leq \min\{1, \frac{2}{1-\alpha} \overline{\dim}_B(S)\}.$$  

Similarly for $p = \infty$

$$\overline{\dim}_M(S) \leq \inf_{L > 0} \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_\sigma(S)} r_{\mathcal{B}-\mathcal{H}^\infty_{L,\alpha}}(\mu, \varepsilon) \leq \inf_{L > 0} \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_\sigma(S)} r_{\mathrm{LIN}-\mathcal{H}^\infty_{L,\alpha}}(\mu, \varepsilon) \leq \min\{1, \frac{2}{1-\alpha} \overline{\dim}_B(S)\}.$$  

For the proof of Theorem V.B.1 see Section IX.B.

The second upper bound concerns the setting of Theorem V.A.1: Borel compression and $(L, \alpha)$-Hölder decompression. It is a universal upper bound, independent of $\mathcal{S}$. Moreover, the compressor and decompressor functions are independent of the choice of measure $\mu \in \mathcal{P}_\sigma(S)$ and operate with zero-probability error.

**Proposition V.B.3.** Let $S \subset [0,1]^Z$ be a subshift. Then for every $0 < \alpha \leq 1$ and $p \in [1, \infty]$  

$$\inf_{L > 0} r_{\mathcal{B}-\mathcal{H}^p_{L,\alpha}}(S, 0) \leq \alpha.$$  

Note that this upper bound is general in a sense that it does not depend on $\mathcal{S}$ (in particular, it is true for the full shift $\mathcal{S} = [0,1]^Z$). The proof is based on the existence of Hölder surjective maps between unit cubes (constructions akin to the Peano curve construction). See Section IX.C.

Proposition V.B.3 together with Theorem V.A.1 gives the following inequalities.

**Corollary V.B.4.** Let $S \subset [0,1]^Z$ be a subshift. For every $0 < \alpha \leq 1$ and $p \in [1, \infty)$ the following holds:

$$\alpha \overline{\dim}_M(S) \leq \inf_{L > 0} \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_\sigma(S)} r_{\mathcal{B}-\mathcal{H}^p_{L,\alpha}}(\mu, \varepsilon) \leq \inf_{L > 0} \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_\sigma(S)} r_{\mathcal{B}-\mathcal{H}^p_{L,\alpha}}(\mu, \varepsilon) \leq \inf_{L > 0} \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_\sigma(S)} r_{\mathrm{LIN}-\mathcal{H}^p_{L,\alpha}}(\mu, \varepsilon) \leq \min\{1, \frac{2}{1-\alpha} \overline{\dim}_B(S)\}.$$  

In particular, if $\overline{\dim}_M(S) = 1$, then the above compression rates are all equal to $\alpha$.

VI. Examples

In this section we present several examples illustrating results of the previous section. For the proofs and calculations see Appendix E.

VI.A. Discrete signals. In general, equality does not hold in Theorem V.A.1.

**Example VI.A.1.** Let $S := \{0,1\}^Z$. Then $\overline{\dim}_M(S) = \dim_B(\{0,1\}) = 0$ (see Example IV.C.1). For any $\alpha \in (0,1]$ and $L > 0$ it holds that

$$\sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_\sigma(S)} r_{\mathcal{B}-\mathcal{H}^1_{L,\alpha}}(\mu, \varepsilon) \geq \frac{\alpha(1 - H(\frac{1}{2}))}{\log(\max\{8L, 8\})} > 0,$$

where $H(p) = -p \log(p) - (1-p) \log(1-p)$ is the Shannon entropy of the probability vector $(p, 1-p)$. For the proof of (6) see Appendix E.B.

\[ \blacksquare \]
This example shows that equality in Theorem V.A.1 might not hold for any fixed \( L > 0 \). Note however that the above lower bound tends to 0 as \( L \to \infty \).

The next example shows that one cannot change the class \( \mathcal{H}_{L,\alpha}^0 \) to \( \mathcal{H}_\alpha \) in Theorem V.A.1.

**Example VI.A.2.** Let \( A = \{ \frac{1}{n} : n \in \mathbb{N} \} \) and \( \mathcal{S} := A^\mathbb{Z} \). Then, according to Example IV.C.1 and [37, Example 2.7]

\[
\dim_M(\mathcal{S}) = \dim_B(\mathcal{S}) = \dim_B(A) = \frac{1}{2}.
\]

On the other hand, we will prove

\[
\sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_\sigma(\mathcal{S})} r_{\mathcal{B} - \mathcal{H}_\alpha}(\mu, \varepsilon) = 0 \quad \text{for every } \alpha \in (0, 1].
\]

Actually, a stronger claim is true:

\[
\sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_\sigma(\mathcal{S})} r_{\text{LIN} - \mathcal{L}}(\mu, \varepsilon) = 0.
\]

For the proof of above statements see Appendix E.C.

**VI.B. Sparse signals.** It turns out that the lower bound in Theorem V.A.1 is tight (after taking infimum over Lipschitz constants, i.e. letting \( L \to \infty \)) in the case of subshifts consisting of \((N, K)\)-sparse vectors.

**Example VI.B.1.** Let \( \mathcal{S} \subset [0, 1]^\mathbb{Z} \) be the subshift from Example IV.C.3, i.e.

\[
\mathcal{S} = \{ x \in [0, 1]^\mathbb{Z} : \forall j \in \mathbb{Z} \| x \|_{j+N-1} \|_0 \leq K \}
\]

for \( N, K \in \mathbb{N}, \; K \leq N \). Recall that \( \dim_M(\mathcal{S}) = \dim_B(\mathcal{S}) = \frac{K}{N} \). For every \( p \in [1, \infty) \) and \( \alpha \in (0, 1] \) it holds

\[
\inf_{L > 0} \sup_{\mu \in \mathcal{P}_\sigma(\mathcal{S})} \sup_{\varepsilon > 0} r_{\mathcal{B} - \mathcal{H}_\alpha}(\mu, \varepsilon) = \inf_{L > 0} r_{\mathcal{B} - \mathcal{H}_\alpha}(\mathcal{S}, 0) = \alpha \dim_M(\mathcal{S}) = \frac{\alpha K}{N}.
\]

For the proof see Appendix E.D. ■

Such strong compression properties are, similarly as in Proposition V.B.3, obtained by employing constructions akin to the Peano curve construction between unit cubes.

The following example gives a lower bound on compression rates for the linear compression with Hölder decompression in case of the \((N, K)\)-sparse subshift. It does not match the upper bound from Theorem V.B.1, but it shows that one cannot improve (in general) the constant \( \frac{2}{1-\alpha} \) to \( \frac{1}{1-\alpha} \) for any \( t < 2 \).

**Example VI.B.2.** Let \( \mathcal{S} \subset [0, 1]^\mathbb{Z} \) be the subshift from Example IV.C.3, i.e.

\[
\mathcal{S} = \{ x \in [0, 1]^\mathbb{Z} : \forall j \in \mathbb{Z} \| x \|_{j+N-1} \|_0 \leq K \}
\]

for \( K, N \in \mathbb{N}, \; K \leq N \). For any \( \alpha \in (0, 1] \) inequality

\[
\sup_{\mu \in \mathcal{P}_\sigma(\mathcal{S})} r_{\text{LIN} - \mathcal{H}_\alpha}(\mu, 0) \geq \min \left\{ \frac{2K}{N}, 1 \right\} = \min \{2 \dim_M(\mathcal{S}), 1\}
\]

holds. Consequently, for every \( p \in [1, \infty] \)

\[
\min \{2 \dim_M(\mathcal{S}), 1\} \leq \inf_{L > 0} \sup_{\mu \in \mathcal{P}_\sigma(\mathcal{S})} r_{\text{LIN} - \mathcal{H}_\alpha}(\mathcal{S}, 0) \leq \min \{\frac{2}{1-\alpha}, \dim_M(\mathcal{S})\}.
\]

For the proof see Appendix E.E. Let us emphasize that the proof of (8) does not use any other properties of \( \alpha \)-Hölder maps than continuity. Therefore the lower bound (8) holds also for merely continuous decompressors. ■
In this section we present the main tool of the proof of Theorem V.A.1: a variational principle for metric mean dimension, which expresses the metric mean dimension of a subshift $\mathcal{S}$ in terms of rate-distortion functions corresponding to the stationary stochastic processes supported in $\mathcal{S}$. It was proved by Lindenstrauss and Tsukamoto in [27]. We present its formulation which is suitable for our applications. It differs slightly from the one in [27]. In Appendix C we deduce the formulation below from the original result of [27].

**VII.A. Rate-distortion function.** The information-theoretic notion used in the formulation of the variational principle is the *rate-distortion function*. We provide a slight modification of the expression used in [27], better suited for the setting of subshifts (and closer to the standard definition, see e.g. [28]). We state the definition for subshifts with alphabet space being a general compact metric space (see e.g. [28]).

**Definition VII.A.1.** Let $(A,d)$ be a compact metric space. Let $\mathcal{S} \subset A^\mathbb{Z}$ be a subshift and $\mu \in \mathcal{P}_\sigma(\mathcal{S})$. For $p \in [1, \infty)$, $\varepsilon > 0$ and $n \in \mathbb{N}$ we define the $L^p$ rate-distortion function $R_{\mu,p}(n,\varepsilon)$ as the infimum of

$$I(X;Y)/n,$$

where $X = (X_0, \ldots, X_{n-1})$ and $Y = (Y_0, \ldots, Y_{n-1})$ are random variables defined on some probability space $(\Omega, \mathcal{F})$ such that

- $X = (X_0, \ldots, X_{n-1})$ takes values in $A^n$, and its law is given by $(\pi_n)_\ast \mu$.
- $Y = (Y_0, \ldots, Y_{n-1})$ takes values in $A^n$ and approximates $(X_0, X_1, \ldots, X_{n-1})$ in the sense that

$$\mathbb{E} \left( \frac{1}{n} \sum_{k=0}^{n-1} d(X_k, Y_k)^p \right) \leq \varepsilon^p.$$

Here $\mathbb{E}(\cdot)$ is the expectation with respect to the probability measure $\mathbb{P}$ and $I(X;Y)$ is the mutual information of random vectors $X$ and $Y$ (see [28] and [27]). As proved in [40, Theorem 9.6.1], the sequence $n \mapsto nR_{\mu,p}(n,\varepsilon)$ is subadditive. [40] provides a proof for stationary stochastic processes with finite alphabet, but it extends verbatim to our setting. Hence, we can define

$$R_{\mu,p}(\varepsilon) = \lim_{n \to \infty} R_{\mu,p}(n,\varepsilon) = \inf_{n \in \mathbb{N}} R_{\mu,p}(n,\varepsilon).$$

**Remark VII.A.2.** Similarly to [27, Remark IV.3], in Definition VII.A.1 it is enough to consider random vectors $Y$ taking only finitely many values. As $I(X;Y) \leq H(Y) < \infty$ for $Y$ taking finitely many values, we obtain that $R_{\mu,p}(\varepsilon) < \infty$ for every $\varepsilon > 0$ (see also Remark C.A.4). Note that $R_{\mu,1}(\varepsilon) \leq R_{\mu,p}(\varepsilon)$ for $p \in [1, \infty)$ and $\varepsilon \geq 0$. For more details on the rate-distortion function see [28, 40].

**VII.B. Variational principle for metric mean dimension.** The following theorem is a variant of the variational principle for metric mean dimension for subshifts $\mathcal{S} \subset [0,1]^\mathbb{Z}$. It is deduced from the original theorem in [27] - see Appendix C.

**Theorem VII.B.1.** Let $\mathcal{S} \subset [0,1]^\mathbb{Z}$ be a subshift. Then for $p \in [1, \infty)$

$$\overline{\text{mdim}}_M(\mathcal{S}) = \limsup_{\varepsilon \to 0} \frac{\sup_{\mu \in \mathcal{P}_\sigma(\mathcal{S})} R_{\mu,p}(\varepsilon)}{\log \frac{1}{\varepsilon}}.$$

**VIII. Related works**

In this section we discuss results by other authors which aim at establishing analog compression rates in various settings, together with corresponding compression-decompression algorithms. The main difference with our work is that these results give bounds on compression rates for a fixed distribution $\mu \in \mathcal{P}_\sigma([0,1]^\mathbb{Z})$ rather than all distributions supported by a given subshift. The bounds are given in terms of notions which can be seen as probabilistic notions of mean dimension.
In their pioneering article [2] Wu and Verdú calculated or bounded from below or above $r_{C-D}(\mu, \varepsilon)$ for certain $C,D$ and $\mu \in \mathcal{P}_\sigma(\mathbb{R}^k)$. The notion which appears in the bounds is the Minkowski-dimension compression rate, which (similarly to metric mean dimension and mean box dimension) is based on the geometrical notion of the box-counting (Minkowski) dimension.

**Definition VIII.1.** [2, Definition 10] For a subshift $S \subset [0,1]^Z$, invariant measure $\mu \in \mathcal{P}_\sigma(S)$ and $0 \leq \varepsilon < 1$ define the Minkowski-dimension compression rate as

$$R_B(\mu, \varepsilon) = \limsup_{n \to \infty} \inf \left\{ \frac{\dim_B(A)}{n} : A \subset [0,1]^n, A \text{ - compact, } \mu(\pi_n^{-1}(A)) \geq 1 - \varepsilon \right\}.$$ 

One can bound the Minkowski-dimension compression rate from above by mean box dimension. More precisely, the following inequalities hold for every subshift $S \subset [0,1]^Z$, $\mu \in \mathcal{P}_\sigma(S)$ and $0 \leq \varepsilon < 1$

$$R_B(\mu, \varepsilon) \leq R_B(\mu, 0) \leq \overline{\dim_B}(S).$$

Similarly to Theorems V.A.1 and V.B.1, Wu and Verdú give lower bounds for Borel-Hölder compression scheme and upper bounds for linear-Hölder compression scheme. Note that they work with the class $H_\alpha$ instead of $H_{p,\alpha}$, hence their results do not guarantee a uniform bound on the Lipschitz constant among the sequence of decoders.

**Theorem VIII.2.** [2, Eq. (75) and Theorem 18] For $\mu \in \mathcal{P}_\sigma[0,1]^Z$, $\varepsilon \in (0,1)$ and $\alpha \in (0,1)$ the following holds:

$$\alpha R_B(\mu, \varepsilon) \leq r_{B-H}(\mu, \varepsilon) \leq r_{LIN-H}(\mu, \varepsilon) \leq \frac{1}{1 - \alpha} R_B(\mu, \varepsilon).$$

**Consequently,**

$$r_{LIN-H}(\mu, \varepsilon) \leq R_B(\mu, \varepsilon).$$

Our Corollary V.B.2 can be seen as a uniform analog of the above result. Note that in Corollary V.B.2 the constant in the upper bound is worse: $\frac{2}{1 - \alpha}$ instead of $\frac{1}{1 - \alpha}$. This is a consequence of considering the zero-probability error case and, as shown in Example VI.B.2, cannot be improved. Note also that the upper bound of Theorem VIII.2 together with (12) imply

$$\sup_{\mu \in \mathcal{P}_\sigma(S)} \sup_{\varepsilon > 0} r_{LIN-H}(\mu, \varepsilon) \leq \frac{1}{1 - \alpha} \overline{\dim_B}(S),$$

yet this is not enough to obtain a similar bound with $H_{p,\alpha}$ replacing $H_\alpha$, as this would require assuring that the Lipschitz constant $L$ is uniformly bounded among the sequence of decompressors achieving the upper bound in Theorem VIII.2. Wu and Verdú proved in [2] the lower bound only for Lipschitz decompressors. For the convenience of the reader, we include the proof for Hölder decompressors in Appendix F (see Proposition F.1). The upper bound on $r_{LIN-H}(\mu, \varepsilon)$ comes from minimizing $R$ in [2, (172)] for fixed $\beta$. Stronger result than the existence of linear compressor and Hölder decompressor was proven in [8], where it is shown that almost every linear transformation of rank large enough serves as a good compressor in this setting. Namely, the authors proved that for every $\eta > 0$, Lebesgue almost every matrix $A \in \mathbb{R}^{n \times k}$ with $k \geq (\frac{1}{1 - \alpha} R_B(\mu, \varepsilon) + \eta)n$ admits an $\alpha$-Hölder decompressor $g : \mathbb{R}^k \to \mathbb{R}^n$ satisfying

$$\mu(\{x \in X \mid g \circ A(x)|_{[0]}^{n-1} \neq x|_{[0]}^{n-1} \}) \leq \varepsilon.$$ 

For details see [8, Subsection VIII]. Similar results for signal separation have been obtained in [7] and [8].

**Remark VIII.3.** We assume the compressor functions to take values in the unit cube $[0,1]^k$, hence we assume an universal bound on signals after compression. Results in [2] are stated with the compressor taking values in $\mathbb{R}^k$, but note that (since we consider compact spaces) composing with suitable affine transformations will give compressor functions with values in $[0,1]^k$ with the same Hölder exponent $\alpha$ of the decompressor and possibly different (but not arbitrary) Lipschitz constant $L$.

Let us discuss now results of [6, 5]. This requires introducing one more type of compression rate.
**Definition VIII.4.** Let $\mu \in \mathcal{P}_\sigma([0,1]^2)$. Let $\mathcal{C}, \mathcal{D} \subset \{ f : [0,1]^n \rightarrow [0,1]^k : n,k \in \mathbb{N} \}$ be regularity classes with respect to the norm $\| \cdot \|_p$. For $n \in \mathbb{N}$ and $\varepsilon \geq 0$, $\delta \geq 0$, the $\mathcal{C} - \mathcal{D}$ probability analog compression rate $r_{\mathcal{C} - \mathcal{D}}^{\mathcal{P}_p}(\mu, \varepsilon, n, \delta) \geq 0$ of $\mu$ with $n$-block error probability $\delta$ at scale $\varepsilon$ is the infimum of

$$\frac{k}{n},$$

where $k$ runs over all natural numbers such that there exist maps $f : [0,1]^n \rightarrow [0,1]^k$, $f \in \mathcal{C}$ and $g : [0,1]^k \rightarrow [0,1]^n$, $g \in \mathcal{D}$ with

$$\mu(\{ x \in [0,1]^2 : \| x_0^{n-1} - g \circ f(x_0^{n-1}) \|_p \geq \varepsilon \}) \leq \delta.$$

Define further:

$$r_{\mathcal{C} - \mathcal{D}}^{\mathcal{P}_p}(\mu, \varepsilon, n, \delta) = \lim_{\delta \rightarrow 0} r_{\mathcal{C} - \mathcal{D}}^{\mathcal{P}_p}(\mu, \varepsilon, n, \delta),$$

$$r_{\mathcal{C} - \mathcal{D}}^{\mathcal{P}_p}(\mu, \varepsilon) = \limsup_{n \rightarrow \infty} r_{\mathcal{C} - \mathcal{D}}^{\mathcal{P}_p}(\mu, \varepsilon, n).$$

Note that if $\mathcal{C}, \mathcal{D}$ are regularity classes with respect to the norm $\| \cdot \|_p$ for $p \in [1, \infty)$, then for any $\varepsilon' > \varepsilon \geq 0$

$$r_{\mathcal{C} - \mathcal{D}}^{\mathcal{P}_p}(\mu, \varepsilon') \leq r_{\mathcal{C} - \mathcal{D}}^{\mathcal{P}_p}(\mu, \varepsilon).$$

This follows from the observation that condition $\mu(\{ x \in [0,1]^2 : \| x_0^{n-1} - g \circ f(x_0^{n-1}) \|_p \geq \varepsilon \}) \leq \delta$ implies $\int_{[0,1]^n} \| x - g \circ f(x) \|_p^\delta \mathcal{D}(\pi_n)_\ast \mu \leq \delta + \varepsilon \mathcal{P}_p^\delta(\varepsilon')^p$ for $\delta$ small enough.

The results of [6] are given in terms of the rate-distortion dimension of a measure $\mu \in \mathcal{P}_\sigma([0,1]^2)$, defined as

$$\overline{\dim}_R(\mu) = \sup_{\varepsilon > 0} \frac{\overline{\dim}_R(\mu, \varepsilon)}{\log \frac{1}{\varepsilon}},$$

where $\overline{\dim}_R(\mu, \varepsilon)$ is the $L^2$ rate-distortion function (see Definition VII.A.1). In [6] results on analog compression in terms of the rate-distortion dimension are obtained using the techniques of compressed sensing. The authors consider a linear compression algorithm in which decompression (given via a suitable minimization problem) is based on a sequence of compression codes with distortion approaching zero. These codes depend on the process and are assumed to be known a priori. In our notation, the authors obtained the following result.

**Theorem VIII.5.** [6, Corollary 2] Let $\mu \in \mathcal{P}_\sigma([0,1]^2)$. Then

$$\overline{\dim}_R(\mu) = \sup_{\varepsilon > 0} r_{\mathcal{P}_p}^{\mathcal{P}_p}(\mu, \varepsilon) \leq \overline{\dim}_R(\mathcal{P}_p) \mu.$$ 

**Remark VIII.6.** In applications, the measure governing the source is not always known, hence one may not have an access to the compression codes required in [6]. A universal algorithm for a certain class of processes was proposed by Jalali and Poor in [5]. For a measure $\mu \in \mathcal{P}_\sigma([0,1]^2)$ define its upper information dimension as

$$\overline{\dim}(\mu) = \lim_{n \rightarrow \infty} \overline{\dim}(\mu, \varepsilon),$$

where $\overline{\dim}(\mu, \varepsilon)$ is the upper Rényi information dimension of the measure $\mathcal{P}_p^\delta(\varepsilon')^p$ on $[0,1]^n$ (see [5, Section IV] for details). In terms of analog compression rates, [5, Theorems 7,8] give the following bound (for the definition of $\psi^\varepsilon$-mixing see [5, Definition 3]):

$$\overline{\dim}(\mu) \leq \sup_{\varepsilon > 0} r_{\mathcal{P}_p}^{\mathcal{P}_p}(\mu, \varepsilon) \leq \overline{\dim}(\mu, \varepsilon) \leq \overline{\dim}(\mathcal{P}_p) \mu.$$

Theorem VIII.5 is stronger than (15). Indeed, in general $\overline{\dim}_R(\mu) \leq \overline{\dim}(\mathcal{P}_p) \mu$ (see [9, Theorem 14]) and the equality can be strict (see [41, Example 1]). Also, $\psi^\varepsilon$-mixing is a quite restrictive assumption. However, inequality (15) does not reflect the full substance of the original results of [5]. Jalali and Poor proved more than merely existence of suitable linear compressors. More precisely, they proved that for any $\eta > 0$, if $(X_n)_{n \in \mathbb{Z}}$ is a $\psi^\varepsilon$-mixing stochastic process with distribution $\mu$
and $A_n \in \mathbb{R}^{n \times m_n}$ are independent random matrices with entries drawn i.i.d according to $\mathcal{N}(0, 1)$ and independently from $(X_n)_{n \in \mathbb{Z}}$ with $\frac{m_n}{n} \geq (1 + \eta)\overline{d}_0(\mu)$, then

$$\|X_0^{n-1} - g_n \circ A_n(X_0^{n-1})\|_2 \xrightarrow{n \to \infty} 0 \text{ in probability}$$

for some explicitly defined Borel functions $g_n : \mathbb{R}^{m_n} \to \mathbb{R}^n$ (depending only on $A_n$). Hence, for such a random sequence of matrices, the expected value

$$\mathbb{E}_\mu(\{x \in X : \|x_0^{n-1} - g_n \circ A_n(x_0^{n-1})\|_2 \geq \varepsilon\})$$

tends to zero as $n \to \infty$ for any $\psi^*$-mixing measure $\mu \in \mathcal{P}_\sigma([0, 1]^\mathbb{Z})$. Inequality (15) follows from this, since for any $\delta > 0$ and $n$ large enough, there exists $A_n \in \mathbb{R}^{n \times m_n}$ satisfying

$$\mu(\{x \in X : \|x_0^{n-1} - g_n \circ A_n(x_0^{n-1})\|_2 \geq \varepsilon\}) \leq \delta.$$  

Decompressors $g_n$ are defined via a certain minimization problem (which makes the decomposition algorithm implementable, though not efficient (cf. [5, Remark 3])). The authors proved also that, in a certain setting, such a compression scheme is robust to noise. More precisely, they proved ([5, Theorems 9 and 10])

$$\|X_0^{n-1} - g_n(A_nX_0^{n-1} + Z_n)\|_2 \xrightarrow{n \to \infty} 0 \text{ in probability}$$

as long as $A_n \in \mathbb{R}^{n \times m_n}$ has i.i.d entries distributed according to $\mathcal{N}(0, \frac{1}{n})$ and $(Z_n)_{n \in \mathbb{N}_0}$ is a stochastic process converging to zero in probability fast enough. Since the functions $g_n$, defined by a certain minimization problem, take only finitely many values, they cannot be taken to be continuous. The strength of the result is the universality of the compression scheme, which is designed without any prior knowledge of the distribution $\mu$: a random Gaussian matrix will serve as a good compressor as long as the rate is at least $\overline{d}_0(\mu)$ and the decompressor is explicit. However, it does not follow that one can choose a sequence of matrices $A_n$ satisfying (16) for all $\psi^*$-mixing measures $\mu$ with $\overline{d}_0(\mu) \leq d$ for some $d \in [0, 1]$.

We are also able to prove a lower bound on $\sup_{\varepsilon > 0} R_{B-H^\alpha_{L^p}}(\mu, \varepsilon)$ for a fixed measure $\mu$ in terms of rate-distortion dimension $\overline{\text{dim}}_R(\mu)$ (see Corollary IX.A.1). It turns out that $\overline{\text{dim}}_R$ is equal to the information dimension rate $\overline{d}(\mu)$ introduced in [41]. Under certain assumptions both of them coincide with $\overline{d}_0(\mu)$. See Section [9, Section VI] for a comprehensive discussion and [9, Section VI] for more on the operational meaning of the information dimensions $\overline{d}(\mu)$ and $\overline{d}_0(\mu)$.

IX. PROOFS OF THE MAIN RESULTS

IX.A. Proof of Theorem V.A.1. Theorem V.A.1 is a direct consequence of Theorem VII.B.1, inequality (3) and Theorem IXA.1 below. The latter one is of independent interest, as it gives a lower bound for compression rates $R_{B-H^\alpha_{L^p}}(\mu, \varepsilon)$ and $r_{B-H^\infty_{L^p}}(\mu, \varepsilon)$ for fixed $\mu \in \mathcal{P}_\sigma(S)$ and $\varepsilon > 0$ (see also Corollary IX.A.2 below).

Theorem IX.A.1. Let $S \subset [0, 1]^\mathbb{Z}$ be closed and shift-invariant. The following holds for $\mu \in \mathcal{P}_\sigma(S)$, $0 < \alpha \leq 1$, $L > 0$ and $p \in [1, \infty)$:

$$R_{\mu,p}(\frac{\|L \varepsilon^\alpha\|_p}{\log(|\frac{1}{L}|)}) \leq \overline{r}_{B-H^\alpha_{L^p}}(\mu, \varepsilon).$$

Similarly, for $p = \infty$ the following holds

$$R_{\mu,1}(\frac{L \varepsilon^\alpha}{\log(|\frac{1}{L}|)}) \leq \overline{r}_{B-H^\alpha_{L^\infty}}(\mu, \varepsilon).$$

Proof. Let us begin with proving the first assertion (for $p < \infty$). Fix $\delta, \varepsilon > 0$. By the definition of $\overline{r}_{B-H^\alpha_{L^p}}(\mu, \varepsilon)$, one may find $k, n \in \mathbb{N}$ with $\frac{k}{n} \leq \overline{r}_{B-H^\alpha_{L^p}}(\mu, \varepsilon) + \delta$ and functions $f : [0, 1]^n \to \mathbb{R}$.
\[ [0,1]^k, \, f \in \mathcal{B}, \, g : [0,1]^k \to [0,1]^n, \, g \in \mathcal{H}^p_{L,\alpha} \text{ such that} \]
\[
(17) \quad \int_{[0,1]^n} \|x - g \circ f(x)\|_p^p d(\pi_n)_* \mu(x) \leq \varepsilon^p.
\]

Regularly partition \([0,1]^k\) into \(\lceil \frac{1}{\varepsilon} \rceil^k\) cubes of side \(\lceil \frac{1}{\varepsilon} \rceil^{-1}\) Borel-wise (thus every point in \([0,1]^k\) is associated by a Borel selector to exactly one cube with edge length \(\lceil \frac{1}{\varepsilon} \rceil^{-1}\) which contains it) and let \(c : [0,1]^k \to F\) associate to each point the center of its cube. Note that \(|\# F| = \lceil \frac{1}{\varepsilon} \rceil^k\) and \(\|x - c(x)\|_p \leq \|x - c(x)\|_\infty \leq \frac{\varepsilon}{2}\) for all \(x \in [0,1]^k\). Define \(Y : [0,1]^n \to [0,1]^n\) by
\[
Y(p) = g(c(f(p))).
\]
and \(X : [0,1]^n \to [0,1]^n\) by \(X = \text{id}\). This gives a pair of random vectors on the probability space \(([0,1]^n, (\pi_n)_* \mu)\). We now estimate:
\[
\mathbb{E}_\mu \|(X_0, X_1, \ldots, X_{n-1}) - (Y_0, Y_1, \ldots, Y_{n-1})\|_1^p = \int_{[0,1]^n} \|x - g \circ c \circ f(x)\|_p^p d(\pi_n)_* \mu(x) \leq \varepsilon^p + \int_{[0,1]^n} L^p \|f(x) - c \circ f(x)\|_{\text{Borel}}^p d(\pi_n)_* \mu(x) \leq \varepsilon^p + L^p \frac{\varepsilon^p}{2^\alpha}.
\]

This implies that we have found \(X, Y\) obeying condition (10) at scale \((\varepsilon^p + L^p \frac{\varepsilon^p}{2^\alpha})^{\frac{1}{p}} = \left(\frac{L^p}{2^\alpha} + \varepsilon^{p(1-\alpha)}\right)^{\frac{1}{p}}\varepsilon^\alpha\), hence
\[
R_{\mu,p}(\frac{L^p}{2^\alpha} + \varepsilon^{p(1-\alpha)}\varepsilon^\alpha) \leq \frac{1}{n} I(X; Y) \leq \frac{1}{n} \mathcal{H}(Y) \leq \frac{\log(\lceil\frac{1}{\varepsilon}\rceil^k)}{n} = \frac{k \log(\lceil\frac{1}{\varepsilon}\rceil)}{n} \leq \log(\lceil\frac{1}{\varepsilon}\rceil)(r^p_{B-\mathcal{H}_{L,\alpha}}(\mu, \varepsilon) + \delta).
\]
We end the proof by dividing by \(\log(\lceil\frac{1}{\varepsilon}\rceil)\).

For \(p = \infty\) one considers the same construction, but functions \(f\) and \(g\) belong now to \(\mathcal{B}\) and \(\mathcal{H}^\infty_{L,\alpha}\) respectively and satisfy
\[
\mu(\{x \in X : g \circ f(x)^{\alpha-1} \neq x^\alpha \}) \leq \varepsilon
\]
instead of (17). Defining \(X, Y\) as before, we have
\[
\mathbb{E}_\mu \|(X_0, X_1, \ldots, X_{n-1}) - (Y_0, Y_1, \ldots, Y_{n-1})\|_1 \leq \varepsilon + \int_{[0,1]^n} L \|f(x) - c \circ f(x)\|_{\infty}^\alpha d(\pi_n)_* \mu(x) \leq \varepsilon + L^\alpha \frac{\varepsilon^\alpha}{2^\alpha}.
\]
This implies
\[
R_{\mu,1}(\frac{L^\alpha}{2^\alpha} + \varepsilon^{1-\alpha})^{\frac{1}{\alpha}} \leq \frac{1}{n} I(X; Y) \leq \frac{1}{n} \mathcal{H}(Y) \leq \frac{\log(\lceil\frac{1}{\varepsilon}\rceil^k)}{n} = \frac{k \log(\lceil\frac{1}{\varepsilon}\rceil)}{n} \leq \log(\lceil\frac{1}{\varepsilon}\rceil)(r^\infty_{B-\mathcal{H}_{L,\alpha}}(\mu, \varepsilon) + \delta).
\]

**Corollary IX.A.2.** Let \(\mu \in \mathcal{P}_\alpha([0,1]^2), \quad \alpha \in (0,1], \quad L > 0\). Then (recall (14) for the definition of \(\dim_R(\mu)\))
\[
(18) \quad \alpha \dim_R(\mu) \leq r_{B-\mathcal{H}^2_{L,\alpha}}^L(\mu).
\]
Remark IX.A.3. Note that taking supremum over $\mu \in \mathcal{P}_\sigma(S)$ in (18) yields
\[
\sup_{\mu \in \mathcal{P}_\sigma(S)} \alpha \dim_B(\mu) \leq \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_\sigma(S)} \frac{r_{\mathcal{L}^2_{-\mathcal{H}^{\alpha}_{L,n}}}(\mu, \varepsilon)}{r_{\mathcal{L}^2_{-\mathcal{H}^{\alpha}_{L,n}}}(\mu, \varepsilon)}.
\]
This, however, does not imply Theorem V.A.1, since there are systems with
\[
\sup_{\mu \in \mathcal{P}_\sigma(S)} \limsup_{\varepsilon \to 0} \frac{R_{\mu,2}(\varepsilon)}{\log \frac{1}{\varepsilon}} < \alpha \dim_M(S)
\]
(cf. [27, Section VIII]). In other words, to obtain Theorem V.A.1, the supremum over $\mu \in \mathcal{P}_\sigma(S)$ has to be taken before passing with $\varepsilon$ to zero, as one cannot exchange these two operations in the variational principle.

IX.B. Proof of Theorem V.B.1. In order to develop the upper bound in Theorem V.B.1, we will make use of the embedding theorem for the upper box-counting dimension. Below we present a corollary of [36, Theorem 4.3] (with proof attributed to [42], based on an earlier result in [22]).

**Theorem IX.B.1.** Let $A$ be a compact subset of $\mathbb{R}^n$ and fix $p \in [1, \infty]$. If $k > \overline{\dim}_B(A)$, then given any $\alpha$ with
\[
0 < \alpha < 1 - \frac{2 \overline{\dim}_B(A)}{k},
\]
for Lebesgue almost every linear map $F \in \text{LIN}(\mathbb{R}^n, \mathbb{R}^k) \simeq \mathbb{R}^{nk}$ there exists $L = L(F, p)$ such that
\[
\|x - y\|_p \leq L\|F(x) - F(y)\|_p^\alpha
\]
for all $x, y \in A$.

In particular, $F$ is one-to-one on $A$ with inverse which is $(L, \alpha)$-Hölder in the norm $\| \cdot \|_p$.

**Remark IX.B.2.** The only manner in which choosing the norm $\| \cdot \|_p$ influences the above theorem is the dependence of the Lipschitz constant $L$ on the norm.

See also [43] for an almost sure embedding theorem for Hausdorff dimension. However, it does not provide Hölder inverse and argues that it cannot exist in general in the probabilistic context. Similar results for the modified lower box-counting dimension have been obtained also in [44].

We will use now Theorem IX.B.1 to prove Theorem V.B.1. Let $S \subset [0, 1]^\mathbb{Z}$ be a subshift. We shall prove
\[
\inf_{L > 0} r_{\text{LIN}-\mathcal{H}^{\alpha}_{L,n}}(S, 0) \leq \frac{2}{1 - \alpha} \text{mdim}_B(S)
\]
for every $0 < \alpha < 1$ and $p \in [1, \infty]$. Fix $\eta > 0$. By Lemma D.1 (applied with $\mathcal{C} = \text{LIN}$) it suffices to prove that there exists $L > 0$ and $n \in \mathbb{N}$ such that
\[
r_{\text{LIN}-\mathcal{H}^{\alpha}_{L,n}}(S, 0, n) \leq \frac{2}{1 - \alpha} \text{mdim}_B(S) + \eta.
\]

Fix $n \in \mathbb{N}$ large enough to obtain $\frac{1}{n} < \frac{\alpha}{2}$ and
\[
\frac{\text{dim}_B(\pi_n(S))}{n} \leq \frac{\text{mdim}_B(S) + \eta(1 - \alpha)}{4}.
\]

By Theorem IX.B.1, if $\alpha \in (0, 1)$ and $k \in \mathbb{N}$, $k > 2 \overline{\dim}_B(\pi_n(S))$ fulfill
\[
\alpha < 1 - \frac{2 \overline{\dim}_B(\pi_n(S))}{k},
\]
then there exists $f : [0, 1]^n \to [0, 1]^k$ in LIN and $L > 0$ such that $f|_{\pi_n(S)}$ is injective with $(L, \alpha)$-Hölder inverse in the norm $\| \cdot \|_p$. According to the Remark III.A.8, $f^{-1} : f(\pi_n(S)) \to [0, 1]^n$ can be extended to function $g : [0, 1]^k \to [0, 1]^n$ belonging to $\mathcal{H}^{\alpha}_{L', \alpha}$ for some $L' \geq L$. We obtain that $r_{\text{LIN}-\mathcal{H}^{\alpha}_{L',\alpha}}(S, 0, n) \leq \frac{\alpha}{k}$ for every such $k$. For fixed $\alpha \in (0, 1)$, condition (22) is satisfied for
\[
k = \left\lceil \frac{2 \overline{\dim}_B(\pi_n(S))}{\alpha} \right\rceil + 1,\]
and hence by (21)
\[
r_{\text{LIN}-\mathcal{H}^{\alpha}_{L',\alpha}}(\mu, 0, n) \leq \frac{1}{n} \left( \left\lceil \frac{2 \overline{\dim}_B(\pi_n(S))}{1 - \alpha} \right\rceil + 1 \right) \leq \frac{1}{n} \left( \frac{2 \overline{\dim}_B(\pi_n(S))}{1 - \alpha} + 2 \right) \leq \frac{2}{1 - \alpha} \left( \frac{\text{mdim}_B(S) + \eta(1 - \alpha)}{4} \right) + \frac{2}{n} \leq \frac{2}{1 - \alpha} \text{mdim}_B(S) + \eta.
\]
Therefore $L'$ and $n$ satisfy (20). This concludes the proof of (19) and Theorem V.B.1.

**Remark IX.B.3.** Example VI.A.1 shows that one cannot improve Theorem V.B.1 by claiming that there exists finite $L > 0$ such that $r_{\text{LIN} - \mathcal{H}_{L,\alpha}^1}(S, 0) \leq \frac{1}{L\alpha} \min_{B}(S)$. Indeed, for $S = \{0, 1\}^\mathbb{Z}$ we have $\min_{B}(S) = 0$, yet for $L > 0$ inequality

$$r_{\text{LIN} - \mathcal{H}_{L,\alpha}^1}(S, 0) \geq \sup_{\varepsilon > 0} \sup_{\mu \in P_\alpha(S)} r_{\mathcal{B} - \mathcal{H}_{L,\alpha}^1}(\mu, \varepsilon) > 0$$

holds.

**IX.C. Proof of Proposition V.B.3.** The proof of Proposition V.B.3 is based on an existence of surjective Hölder maps between unit cubes. It is well known that there exists a surjective $\frac{1}{n}$-Hölder map from $[0, 1]$ onto $[0, 1]^n$ (see [45, Thm. 4.55]). This is a generalization of the classical Peano curve construction (see e.g. [46]). We will use a similar construction to obtain the following proposition:

**Proposition IX.C.1.** For every $n, k \in \mathbb{N}$, $k \leq n$, $p \in [1, \infty]$ and $\alpha < \frac{k}{n}$ there exist maps $f : [0, 1]^n \to [0, 1]^k$ and $g : [0, 1]^k \to [0, 1]^n$ such that $f \in \mathcal{B}$, $g \in \mathcal{H}_\alpha$ and $g \circ f(x) = x$ for every $x \in [0, 1]^n$.

**Proof.** As $\alpha < \frac{k}{n}$, there exists a surjective and $\alpha$-Hölder map $g : [0, 1]^k \to [0, 1]^n$ (see [47, Comments to Problem 1988-5] or [48]). Let $C([0, 1]^k)$ be the space of closed non-empty subsets of $[0, 1]^k$ equipped with the Vietoris topology. Recall that its Borel space $B(C([0, 1]^k))$ is the Effros Borel space of $[0, 1]^k$, i.e. the $\sigma$-algebra generated by the sets of the form $\{F \in C([0, 1]^k) : F \cap U \neq \emptyset\}$ for open $U \subset [0, 1]^k$ ([49, 12.7]). Note that $\mathcal{M} : [0, 1]^n \to C([0, 1]^k)$ given as $\mathcal{M}(x) = g^{-1}(\{x\})$ is Borel, as for every open $U \subset [0, 1]^k$ there is

$$M^{-1}(\{F \in C([0, 1]^k) : F \cap U \neq \emptyset\}) = \{x \in [0, 1]^n : g^{-1}(\{x\}) \in \{F \in C([0, 1]^k) : F \cap U \neq \emptyset\}\} = \{x \in [0, 1]^n : g^{-1}(\{x\}) \cap U \neq \emptyset\} = g(U).$$

The latter set is Borel as $g$ is continuous and $U$ is $F_\alpha$ an open subset of a compact space $[0, 1]^k$.

By the Kuratowski-Ryll-Nardzewski selection theorem ([49, 12.13]) there is a Borel selector $s : C([0, 1]^k) \to [0, 1]^k$ (i.e. a Borel map satisfying $s(A) \in A$ for every $A \in C([0, 1]^k)$). Let $f : [0, 1]^n \to [0, 1]^k$ be given as $f = s \circ M$. Then $f$ is Borel and $g(f(x)) = x$ as $f(x) = s(g^{-1}(\{x\})) \in g^{-1}(\{x\})$. \hfill $\square$

Let us prove now Proposition V.B.3. Let $S \subset [0, 1]^\mathbb{Z}$ be a subshift. Fix $0 < \alpha \leq 1$ and $p \in [1, \infty]$. We shall prove

$$\inf_{L>0} r_{\mathcal{B} - \mathcal{H}_{L,\alpha}^p}(S, 0) \leq \alpha. \tag{23}$$

The inequality is clear for $\alpha = 1$, hence we can assume $\alpha < 1$. Fix arbitrary $\eta > 0$. By Lemma D.1 (applied with $\mathcal{C} = \mathcal{B}$)

$$\inf_{L>0} r_{\mathcal{B} - \mathcal{H}_{L,\alpha}^p}(S, 0) = \inf_{L>0} \inf_{n \in \mathbb{N}} r_{\mathcal{B} - \mathcal{H}_{L,\alpha}^p}(S, 0, n),$$

hence it is enough to prove that there exists $n \in \mathbb{N}$ and $L > 0$ with $r_{\mathcal{B} - \mathcal{H}_{L,\alpha}^p}(S, 0, n) \leq \alpha + \eta$. Let $k, n \in \mathbb{N}$ be such that $k \leq n$ and $\alpha < \frac{k}{n} \leq \alpha + \eta$. By Proposition IX.C.1 there exists $f : [0, 1]^n \to [0, 1]^k$ and $g : [0, 1]^k \to [0, 1]^n$ such that $f \in \mathcal{B}$, $g \in \mathcal{H}_\alpha$ and $g \circ f(x) = x$ for every $x \in [0, 1]^n$. Therefore there exists $L > 0$ such that

$$r_{\mathcal{B} - \mathcal{H}_{L,\alpha}^p}(S, 0, n) \leq \frac{k}{n} \leq \alpha + \eta.$$

As $\eta$ was arbitrary, (23) is proved.
X. Concluding remarks

In this paper, we have considered the problem of finding worst-case compression rates, which are sufficient for all stationary stochastic processes taking values in a given set $\mathcal{S} \subset [0,1]^\mathbb{Z}$, under certain constraints of the compression and decompression process. In the case of Borel compression and $(L,\alpha)$-Hölder decompression (with both parameters fixed among the sequence of decoders), we have obtained a lower bound in terms of the metric mean dimension $\text{mdim}_M(\mathcal{S})$ of the dynamical system $(\mathcal{S},\text{shift})$:

$$\alpha \text{mdim}_M(\mathcal{S}) \leq \sup_{\mu \in \mathcal{P}(\mathcal{S})} \sup_{\varepsilon > 0} r_{\mathcal{S}^* - H_{L,\alpha}}^p(\mathcal{S},\varepsilon).$$

Intuitively, this result states that for a given set of trajectories $\mathcal{S}$, one can always find a stationary stochastic process supported in $\mathcal{S}$, which cannot be compressed at a better rate than $\alpha \text{mdim}_M(\mathcal{S})$. This can be applied whenever geometric information on the signal is given (i.e. one knows $\mathcal{S}$), but its statistics are unknown.

We have obtained also two zero-probability error upper bounds on the compression rates. The first one considers linear compression and Hölder decompression:

$$\inf_{L > 0} r_{\mathcal{S}^* - H_{L,\alpha}}^p(\mathcal{S},0) \leq \frac{2}{1 - \alpha} \text{mdim}_B(\mathcal{S}).$$

It is obtained by applying a finite-dimensional embedding theorem for the upper box-counting dimension. By considering $(N,K)$-sparse subshifts, we have shown that in general the constant $\frac{2}{1 - \alpha} \text{mdim}_B(\mathcal{S})$ above cannot be improved in the zero-probability error case. The second upper bound considers Borel compression and Hölder decompression:

$$\inf_{L > 0} r_{\mathcal{S}^* - H_{L,\alpha}}^p(\mathcal{S},0) \leq \alpha.$$

The proof employs constructions of surjective Hölder maps between unit cubes akin to the Peano curve construction. This type of construction would not be possible for more stringent regularity requirements for the compressor.

This paper introduces notions and techniques from the theory of dynamical systems to the study of analog compression rates. Its main tool is the variational principle of Lindenstrauss and Tsukamoto [27], which had previously established a link between ergodic theory and mean dimension theory.

As our main example, we have considered a parametrized family of sparse signal subshifts for which we proved that the lower bound (24) is in fact an equality (after taking infimum over $L > 0$). Whenever equality holds in (24), it can be seen an operational characterization of metric mean dimension, as well as an answer to the given compression problem. It is therefore desirable to answer the following:

**Problem X.1.** Under what conditions (for which subshifts) does equality hold in (24) (possibly after taking $\inf_{L > 0}$)?

### Appendix A. Metric mean dimension in dynamical systems

In this section we present metric mean dimension in its original setting - the theory of dynamical systems. Recall that by a dynamical system we understand triple $(\mathcal{X},\rho,T)$ consisting of a compact metric space $(\mathcal{X},\rho)$ and a homeomorphism $T : \mathcal{X} \to \mathcal{X}$. First, we introduce the notion of complexity of the system at scale $\varepsilon > 0$.

**Definition A.1.** Let $(\mathcal{X},\rho)$ be a compact metric space and let $T : \mathcal{X} \to \mathcal{X}$ be a homeomorphism. For $n \in \mathbb{N}$ define a metric $\rho_n$ on $\mathcal{X}$ by $\rho_n(x,y) = \max_{0 \leq k < n} \rho(T^k x, T^k y)$. The upper and lower metric mean dimensions of the system $(\mathcal{X},T,\rho)$ are defined as

$$\text{mdim}^u_M(\mathcal{X},T,d) = \limsup_{\varepsilon \to 0} \lim_{n \to \infty} \frac{\log \#(\mathcal{X},\rho_n,\varepsilon)}{n \log \frac{1}{\varepsilon}},$$

and

$$\text{mdim}^l_M(\mathcal{X},T,d) = \liminf_{\varepsilon \to 0} \lim_{n \to \infty} \frac{\log \#(\mathcal{X},\rho_n,\varepsilon)}{n \log \frac{1}{\varepsilon}}.$$
where \( \#(\mathcal{X}, \rho_n, \varepsilon) \) is the \( \varepsilon \)-covering number of \( \mathcal{X} \) with respect to the metric \( \rho_n \) (see Definition IV.A.1). The limit with respect to \( n \) exists due to the subadditivity of the sequence \( n \mapsto \log \#(\mathcal{X}, \rho_n, \varepsilon) \). If the upper and lower limits coincide, then we call its common value the **metric mean dimension** of \((\mathcal{X}, T, \rho)\) and denote it by \( \overline{\text{mdim}}_M(\mathcal{X}, T, \rho) \).

**Remark A.2.** Metric mean dimension is an invariant for \( \text{bi-Lipshitz} \) isomorphisms. Precisely, if \((\mathcal{X}, T, \rho_1)\) and \((\mathcal{Y}, S, \rho_2)\) are dynamical systems and \( \Phi : \mathcal{X} \to \mathcal{Y} \) is a \( \text{bi-Lipshitz} \) bijection (i.e. a Lipshitz map with a Lipshitz inverse) which is equivariant (i.e. it satisfies \( \Phi \circ T = S \circ \Phi \)), then \( \overline{\text{mdim}}_M(\mathcal{X}, T, \rho_1) = \overline{\text{mdim}}_M(\mathcal{Y}, S, \rho_2) \).

A topological version of mean dimension for actions of amenable groups was introduced by Gromov in \cite{29}. This invariant of topological dynamical systems was used by Lindenstrauss and Weiss in \cite{23} to answer a long standing question in topological dynamics: does every minimal system in \cite{29} to answ er a long standing question in topological dynamics: does every minimal system have mean dimension \( \leq 1 \) ? The answer is negative, since any system embeddable in \((([0,1]^Z, \sigma)] \) has topological mean dimension at most one and in \cite{23} a minimal system with mean dimension strictly greater than one was constructed. Moreover, it was proved in \cite{24}, that any minimal system with topological mean dimension strictly smaller than \( \frac{D}{2} \) is embeddable into \(([0,1]^D, \sigma] \). This constant is known to be optimal (cf. \cite{50}). One of the main tools in the proof is a variant of the Whittaker-Nyquist-Kotelhikov-Shannon sampling theorem, which indicates a connection between mean dimension theory and signal processing. For similar results for \( \mathbb{Z}^n \) actions see \cite{26} and \cite{51}. For more on mean topological dimension see \cite{32}. Metric mean dimension was introduced in \cite{23} and proved to be, when calculated with respect to any compatible metric, an upper bound for the topological mean dimension. It was recently successfully used in \cite{52} and \cite{53} to obtain formulas for mean dimension of dynamical systems arising from geometric analysis.

If \( S \subset [0,1]^Z \) is a subshift, then Definition A.1 with the dynamics given by the shift

\[
\sigma : S \to S, \quad \sigma((x_i)_{i=-\infty}^\infty) = (x_{i+1})_{i=-\infty}^\infty
\]

and the metric

\[
\tau(x, y) = \sum_{i=-\infty}^\infty \frac{1}{2^{|i|}} |x_i - y_i|, \quad x, y \in S
\]

gives the same value of metric mean dimension as Definition IV.B.1.

**Proposition A.3.** For a subshift \( S \subset [0,1]^Z \) it holds

\[
\overline{\text{mdim}}_M(S, \sigma, \tau) = \limsup_{\varepsilon \to 0} \lim_{n \to \infty} \frac{\log \#(\tau_n(S), \| \cdot \|_{\infty}, \varepsilon)}{n \log \frac{1}{\varepsilon}}.
\]

For the proof of Proposition A.3 we will use the following lemma:

**Lemma A.4.** Let \( S \subset [0,1]^Z \) be a subshift. Fix \( \varepsilon > 0 \) and \( m \in \mathbb{N} \) such that \( 2^{-m+2} < \varepsilon \). Then for \( n \in \mathbb{N} \) and \( A \subset S \) the inequality

\[
\#(A, \tau_n, 8\varepsilon) \leq \#(\pi_{n-m}^{-1}(A), \| \cdot \|_{\infty}, \varepsilon)
\]

holds (\( \tau_n \) denotes here the dynamical metric \( \tau_n(x, y) = \max_{0 \leq k < n} \tau(\sigma^k x, \sigma^k y)) \).

**Proof.** Let \( E \subset \pi_{(n-m)}^{-1}(A) \) be an \( \varepsilon \)-net (recall Definition IV.A.1) in the metric \( \| \cdot \|_{\infty} \) on \([0,1]^{n+2m} \) with \#E = \#(\pi_{n}^{-m}(A), \| \cdot \|_{\infty}, \varepsilon) \). Take \( D \subset A \) consisting of representatives of sets \((\pi_{n+2m}^{-1}(E))^{-1}(\{x\}) \), \( x \in E \). Then \( D \) is a 4\( \varepsilon \)-net in \( A \) in the metric \( \tau_n \). Indeed, for \( y \in A \), there exists \( x \in D \) such that \( \|\pi_{n}^{-m}(y) - \pi_{n}^{-m}(x)\|_{\infty} < \varepsilon \), hence for \( 0 \leq j < n \) we have

\[
\tau(\sigma^j y, \sigma^j x) \leq 2^{-m+2} + \sum_{|k| < m} \frac{1}{2^k} |y_k - x_k| < 2^{-m+2} + \varepsilon \sum_{|k| < m} \frac{1}{2^k} < 4\varepsilon.
\]

Taking a cover of \( A \) by 4\( \varepsilon \)-balls with centers in \( D \), we obtain the result.

\footnote{A system \((\mathcal{X}, \rho, T)\) is called **minimal** if for every \( x \in \mathcal{X} \), the orbit \( \{T^n x : n \in \mathbb{Z}\} \) is dense in \( \mathcal{X} \).}
Proof. (of Proposition A.3) Observe first that for $x, y \in [0, 1]^Z$, the inequality $\tau_n(x, y) < \varepsilon$ implies $\|\pi_n(x) - \pi_n(y)\|_\infty < \varepsilon$ and hence
\[
\#(\pi_n(S), \| \cdot \|_\infty, \varepsilon) \leq \#(S, \tau_n, \varepsilon).
\]
This gives
\[
\limsup_{\varepsilon \to 0} \lim_{n \to \infty} \frac{\log \#(\pi_n(S), \| \cdot \|_\infty, \varepsilon)}{n \log \frac{1}{\varepsilon}} \leq \limsup_{\varepsilon \to 0} \lim_{n \to \infty} \frac{\log \#(S, \tau_n, \varepsilon)}{n \log \frac{1}{\varepsilon}} = \mdim_M(S, \sigma, \tau).
\]
On the other hand, using Lemma A.4 with $m = \lceil \log \frac{1}{\varepsilon} \rceil + 2$ and submultiplicativity of the function $n \mapsto \#(\pi_n(S), \| \cdot \|_\infty, \varepsilon)$ we obtain
\[
\#(S, \tau_n, 8\varepsilon) \leq \#(\pi_n^{n+m}(S), \| \cdot \|_\infty, \varepsilon) \leq \#(\pi_n(S), \| \cdot \|_\infty, \varepsilon) \#(\pi_m(S), \| \cdot \|_\infty, \varepsilon)^2.
\]
This yields
\[
\lim_{n \to \infty} \frac{\log \#(S, \tau_n, 8\varepsilon)}{n} \leq \lim_{n \to \infty} \frac{\log \#(\pi_n(S), \| \cdot \|_\infty, \varepsilon) + 2 \log \#(\pi_m(S), \| \cdot \|_\infty, \varepsilon)}{n} = \lim_{n \to \infty} \frac{\log \#(\pi_n(S), \| \cdot \|_\infty, \varepsilon)}{n}.
\]
Dividing both sides by $\log \frac{1}{\varepsilon}$ and taking $\limsup$ ends the proof. \[\square\]

Appendix B. Proof of Proposition IV.B.3

We shall prove
\[
\mdim_M(S) \leq \mdim_B(S)
\]
for a subshift $S \subset [0, 1]^Z$. Fix $\eta > 0$. Take $N \in \mathbb{N}$ with \(\frac{1}{\eta} \dim_B(\pi_N(S)) \leq \dim_B(S) + \eta\). Choose $\varepsilon_0 > 0$ such that
\[
\#(\pi_N(S), \| \cdot \|_\infty, \varepsilon) \leq \varepsilon^{-\dim_B(\pi_N(S)) - \eta} \text{ for } 0 < \varepsilon < \varepsilon_0.
\]
Fix $\varepsilon < \varepsilon_0$. By the submultiplicativity of the function $n \mapsto \#(\pi_n(S), \| \cdot \|_\infty, \varepsilon)$, for $k \in \mathbb{N}$ we have
\[
\frac{\log \#(\pi_{kn}(S), \| \cdot \|_\infty, \varepsilon)}{kn} \leq \frac{\log \#(\pi_n(S), \| \cdot \|_\infty, \varepsilon)}{n} \leq \frac{(\dim_B(\pi_N(S)) + \eta) \log \frac{1}{\varepsilon}}{N} \leq \frac{(\dim_B(S) + \eta(1 + \frac{1}{N})) \log \frac{1}{\varepsilon}}{N}.
\]
Therefore
\[
\mdim_M(S) = \limsup_{\varepsilon \to 0} \lim_{n \to \infty} \frac{\log \#(\pi_n(S), \| \cdot \|_\infty, \varepsilon)}{n \log \frac{1}{\varepsilon}} \leq \mdim_B(S) + 2\eta.
\]
As $\eta > 0$ was arbitrary, the proof is finished.

Appendix C. Variational principle - details

The goal of this section is to prove Theorem VII.B.1. It can be easily deduced from the variational principle for metric mean dimension in [27], which is valid for dynamical systems more general than subshifts, once the corresponding rate-distortion functions are compared (see Proposition C.B.1 below). Let us begin by formulating the original result of [27].

C.A. Variational principle for general dynamical systems.

Definition C.A.1. ([27, Condition II.3]) Let $(X, \rho)$ be a compact metric space. It is said to have the tame growth of covering numbers if for every $\delta > 0$ we have
\[
\lim_{\varepsilon \to 0} \varepsilon^\delta \log \#(X, \rho, \varepsilon) = 0.
\]

Remark C.A.2. Lindenstrauss and Tsukamoto observed that $([0, 1]^Z, \tau)$ has the tame growth of covering numbers, since $\log \#([0, 1]^Z, \tau, \varepsilon) = O(\log \varepsilon^2)$.

In [27] the following definition is made:
Definition C.A.3. Let $(\mathcal{X}, T, \rho)$ be a dynamical system and $\mu \in \mathcal{P}_T(\mathcal{X})$. For $p \in [1, \infty)$ and $n \in \mathbb{N}$ define $\hat{R}_{\mu, p}(\varepsilon, n)$ as the infimum of
\[
\frac{I(X; Y)}{n},
\]
where $X$ and $Y = (Y_0, \ldots, Y_{n-1})$ are random variables defined on some probability space $(\Omega, \mathcal{F})$ such that
- $X$ takes values in $\mathcal{X}$ and its law is given by $\mu$.
- Each $Y_k$ takes values in $\mathcal{X}$, and $Y$ approximates the process $(X, TX, \ldots, T^{n-1}X)$ in the sense that
\[
\mathbb{E}
\left(
\frac{1}{n} \sum_{k=0}^{n-1} \rho(T^kX, Y_k)^p\right) < \varepsilon^p.
\]
Similarly as in the Definition VII.A.1, we can make use of the subadditivity of the sequence $n \mapsto n\hat{R}_{\mu, p}(\varepsilon, n)$ (which follows as in [40, Theorem 9.6.1]), to make the following definition:
\[
\hat{R}_{\mu, p}(\varepsilon) = \lim_{n \to \infty} \hat{R}_{\mu, p}(\varepsilon, n) = \inf_{n \in \mathbb{N}} \hat{R}_{\mu, p}(\varepsilon, n).
\]

Remark C.A.4. As pointed out in [27, Remark IV.3], in Definition C.A.3 it is enough to consider random vectors $Y$ taking finitely many values. As $I(X; Y) \leq H(Y) \leq \infty$ for such $Y$, we obtain also $\hat{R}_{\mu, p}(\varepsilon) < \infty$ for every $\varepsilon > 0$.

In this setting, the variational principle for metric mean dimension states the following:

Theorem C.A.5. ([27, Corollary III.6]) Let $(\mathcal{X}, \rho)$ be a compact metric space having the tame growth of covering numbers and let $T : \mathcal{X} \to \mathcal{X}$ be a homeomorphism. Then, for any $p \in [1, \infty)$
\[
\overline{\text{mdim}}_M(\mathcal{X}, T, \rho) = \limsup_{\varepsilon \to 0} \frac{\sup_{\mu \in \mathcal{P}_T(\mathcal{X})} \hat{R}_{\mu, p}(\varepsilon)}{\log \frac{1}{\varepsilon}}
\]
and
\[
\underline{\text{mdim}}_M(\mathcal{X}, T, \rho) = \liminf_{\varepsilon \to 0} \frac{\sup_{\mu \in \mathcal{P}_T(\mathcal{X})} \hat{R}_{\mu, p}(\varepsilon)}{\log \frac{1}{\varepsilon}}.
\]
Velozo and Velozo [39] provided an alternative formulation in terms of Katok entropy. For the extension of the Theorem VII.B.1 to actions of countable discrete amenable groups see [54].

C.B. Proof of Theorem VII.B.1. The difference between our formulation of Theorem VII.B.1 and the original result of Lindenstrauss and Tsukamoto (Theorem C.A.5) is in the use of two different definitions of rate-distortion functions: Theorem VII.B.1 uses $R_{\mu, p}$ as defined in Definition VII.A.1, while Theorem C.A.5 uses $\hat{R}_{\mu, p}$ as defined in Definition C.A.3. The former one is more convenient to work with in the case of subshifts $S \subset A^\mathbb{Z}$, yet it is formally different from the latter one: $R_{\mu, p}$ is defined in terms of the metric $d$ on the alphabet $A$, while $\hat{R}_{\mu, p}$ is defined in terms of the product metric
\[
\rho(x, y) = \sum_{i \in \mathbb{Z}} \frac{d(x_i, y_i)}{2^{|i|}}
\]
on the space $S \subset A^\mathbb{Z}$. Therefore deducing Theorem VII.B.1 from Theorem C.A.5 requires a technical lemma comparing the two rate-distortion functions. Indeed, Theorem VII.B.1 follows Theorem C.A.5, Proposition C.B.1 and Remark C.A.2 below.

The following proposition shows that for a subshift $S \subset [0, 1]^\mathbb{Z}$ considered as a dynamical system $(S, \sigma, \tau)$, the above definition of the rate-distortion function is comparable with the one introduced in Definition VII.A.1.

Proposition C.B.1. Let $(A, d)$ be a compact metric space, $S \subset A^\mathbb{Z}$ a subshift and $\mu \in \mathcal{P}_\sigma(S)$. Then, for any $p \in [1, \infty)$
\[
\tilde{R}_{\mu, p}(14\varepsilon) \leq R_{\mu, p}(\varepsilon) \leq \hat{R}_{\mu, p}(\varepsilon),
\]
where $R_{\mu, p}$ is defined as in Definition VII.A.1, while $\hat{R}_{\mu, p}$ is defined as in Definition C.A.3 with metric $\rho$ given by (26).
Proof. We will first show \( R_{\mu,p}(\varepsilon) \leq \tilde{R}_{\mu,p}(\varepsilon) \). Fix \( \delta > 0 \) and let \( n \in \mathbb{N} \) be such that, \( \tilde{R}_{\mu,p}(\varepsilon, n) < R_{\mu,p}(\varepsilon) + \delta \). In particular we may find random variables \( X \) and \( Y = (Y_0, \ldots, Y_{n-1}) \) taking values in \( \mathcal{S} \) and \( \mathcal{S}^n \) respectively, obeying (25) and satisfying \( \frac{I(X;Y)}{n} < R_{\mu,p}(\varepsilon) + \delta \). Define \( \tilde{X}_k = \pi_0(\sigma^k X) \) and \( \tilde{Y}_k = \pi_0(Y_k) \) for \( k = 0, \ldots, n-1 \). Note that

\[
d(\tilde{Y}_k, \tilde{X}_k) \leq \rho(\sigma^k X, Y_k),
\]

hence \( \tilde{Y} \) obeys (10). Thus \( R_{\mu,p}(\varepsilon) \leq R_{\mu,p}(n, \varepsilon) \leq \frac{I((\tilde{X}_0, \ldots, \tilde{X}_{n-1});(\tilde{Y}_0, \ldots, \tilde{Y}_{n-1})}{n} \leq \frac{I(X;Y)}{n} < R_{\mu,p}(\varepsilon) + \delta \). We have used here the data-processing lemma [27, Lemma 2.2].

We will show now \( \tilde{R}_{\mu,p}(14\varepsilon) \leq R_{\mu,p}(\varepsilon) \). Fix \( \delta > 0 \) and let \( m, n \in \mathbb{N} \) be such that \( 2^{p(-m+2)-1}\text{diam}(A)^p < \varepsilon, \ (3\text{diam}(A))^p \frac{2m}{n} < \varepsilon^p, \ n > 2m \) and \( R_{\mu,p}(\varepsilon, n) < R_{\mu,p}(\varepsilon) + \delta \). In particular for such \( n \) we may find random variables \( X = (\tilde{X}_0, \ldots, \tilde{X}_{n-1}) \) and \( Y = (\tilde{Y}_0, \ldots, \tilde{Y}_{n-1}) \) taking values in \( A^n \), obeying (10) and \( \frac{I(X;Y)}{n} < R_{\mu,p}(\varepsilon) + \delta \). Let us denote by \( d_p \) the metric on \( A^n \) given by

\[
d_p(x, y) = \left( \frac{1}{n} \sum_{i=0}^{n-1} d(x_i, y_i)^p \right)^{\frac{1}{p}}.
\]

Take any Borel map \( S : A^n \to \mathcal{S} \), \( S = (S_i)_{i \in \mathbb{Z}} \) such that for \( x \in A^n \) and \( y = (y_i)_{i \in \mathbb{Z}} \in \mathcal{S} \) the following holds:

\[
d_p(x, \pi_n(S(x))) \leq d_p(x, \pi_n(y)).
\]

Formally, such \( S \) can be constructed as follows. Define \( t : A^n \to \mathbb{R} \) as

\[
t(x) = \min\{d_p(x, \pi_n(y)) : y \in \mathcal{S}\}
\]

(\( t \) is well defined as (\( A, d \) is compact). Let \( C(\mathcal{S}) \) be the space of closed non-empty subsets of \( \mathcal{S} \) equipped with the Vietoris topology. Recall that its Borel space \( B(C(\mathcal{S})) \) is the Effros Borel space of \( \mathcal{S} \), i.e. the \( \sigma \)-algebra generated by the sets of the form \( \{F \in C(\mathcal{S}) : F \cap U \neq \emptyset \} \) for open \( U \subset \mathcal{S} \) ([49, 12.7]). Define \( M : A^n \to C(\mathcal{S}) \) as

\[
M(x) = \{y \in \mathcal{S} : d_p(x, \pi_n(y)) = t(x)\}.
\]

Note that \( M : [0,1]^n \to C(\mathcal{S}) \) is Borel as \( M^{-1}(\{F \in C(\mathcal{S}) \mid F \cap U \neq \emptyset\}) \) is open in \( [0,1]^n \) for all \( U \) open in \( \mathcal{S} \). By the Kuratowski-Ryll-Nardzewski selection theorem ([49, 12.13]) there is a Borel selector \( s : C(\mathcal{S}) \to \mathcal{S} \). Now \( S : A^n \to \mathcal{S} \) defined as \( S(x) = s(M(x)) \) satisfies (28).

Since the distribution of \( X \) is \( (\pi_n)_{\mu} \), there exist random variables \( X = (X_k)_{k \in \mathbb{Z}} \) taking values in \( \mathcal{S} \) with distribution \( \mu \) and \( Z = (Z_0, \ldots, Z_{n-1}) \) taking values in \( A^n \) such that the conditional distributions satisfy \( \Pr(Z \mid \pi_n(X) = x) = \Pr(Y \mid X = x) \). Define random variables \( Y_0, \ldots, Y_{n-1} \) taking values in \( \mathcal{S} \) by \( Y_k = \sigma^k \circ \sigma \circ Z \). Using (28) we obtain

\[
\mathbb{E}(d_p(\pi_n(X), \pi_n(Y_0)))^p = \mathbb{E}(d_p(\pi_n(X), \pi_n(S \circ Z)))^p \leq \mathbb{E}(d_p(\pi_n(X), Z) + d_p(Z, \pi_n(S \circ Z)))^p \leq 2^p\mathbb{E}(d_p(\tilde{X}, \tilde{Y}))^p.
\]

We have the following series of inequalities (see below for explanations)
Inequality (30) follows from equality \( \text{diam}(A^Z) = \text{diam}(A) \), while (31) follows from (26). Inequality (32) is obtained by applying inequality \((a + b)^p \leq 2^{p-1}(a^p + b^p)\) for \( a, b \geq 0, p \in [1, \infty) \) (which follows from Jensen’s inequality [31, Theorem 3.3]). (33) follows from Jensen’s inequality (recall that \( \sum_{i=-\infty}^{\infty} 1/2^n = 3 \)), while (34) follows from (26) and (28). Equality (35) follows from the definition of \( d_p \) (see (27)). Taking the expected value and estimating further we obtain

\[
E \left( \frac{1}{n} \sum_{k=0}^{n-1} \rho(\sigma^k X, Y)^p \right) \leq 2 \varepsilon^p + 3^p 2^{p-1} E \left( d_p(\pi_n(X), \pi_n(Y))^p \right)
\]

(36)

\[
\leq 2 \varepsilon^p + 3^p 2^{2p-1} E(\tilde{X}, \tilde{Y})^p
\]

(37)

\[
\leq (2 + 3^p 2^{2p-1}) \varepsilon^p
\]

\[
\leq (2 + 3^p 2^{2p}) \varepsilon^p \leq (14\varepsilon)^p.
\]

Inequality (36) follows from (29). For (37) recall that \( \tilde{X}, \tilde{Y} \) obey (10). We conclude that \( Y = (Y_0, \ldots, Y_{n-1}) \) obeys (25) with \( 14\varepsilon \). Thus \( \tilde{R}_{\mu,p}(14\varepsilon) \leq \tilde{R}_{\mu,p}(14\varepsilon, n) \leq \frac{I(X, Y)}{n} \leq \frac{I(X, Y)}{n} \leq R_{\mu,p}(\varepsilon) + \delta \). We have used here the data-processing lemma [27, Lemma 2.2].

Remark C.B.2. Theorem VII.B.1 holds true for subshifts \( S \subset A^Z \) for general compact metric space \((A, d)\), as long as \( S \) has the tame growth of covering numbers (see Definition C.A.1). This follows from the fact that Proposition C.B.1 is true in such generality.

APPENDIX D. "Almost subadditivity" lemma

The following lemma shows that, in some cases, the upper limit with respect to \( n \) in the definition of the compression rate can be replaced by an infimum. The proof is based on the fact that, for suitable regularity classes \( \mathcal{C} \) and \( \mathcal{D} \), the sequence \( n \mapsto n_{\mathcal{C} \rightarrow \mathcal{D}}(S, 0, n) \) is "almost subadditive".

**Lemma D.1.** Let \( \mathcal{C} \) be a regularity class such that

- \( \mathcal{C} \) is closed under taking (tensor) products, i.e. if \( f_1 : [0,1]^{n_1} \rightarrow [0,1]^{k_1}, f_2 : [0,1]^{n_2} \rightarrow [0,1]^{k_2} \) belong to \( \mathcal{C} \) then so does \( f : [0,1]^{n_1+n_2} \rightarrow [0,1]^{k_1+k_2} \) given by \( f(x, y) = (f_1(x), f_2(y)) \) for \( x \in [0,1]^{n_1}, y \in [0,1]^{n_2} \),
- the identity id : \([0,1]^n \rightarrow [0,1]^n\) belongs to \( \mathcal{C} \) for every \( n \in \mathbb{N} \).

Then, for every \( p \in [1, \infty], L \geq 1, \alpha \in (0,1] \) and \( \varepsilon > 0 \), the following holds

\[
r_{\mathcal{C} \rightarrow \mathcal{H}_{L+\varepsilon, \alpha}}(S, 0) \leq \inf_{n \in \mathbb{N}} r_{\mathcal{C} \rightarrow \mathcal{H}_L}(S, 0, n).
\]

(38)
Consequently,

\( \inf_{L>0} r_{C-H^p_{L,\alpha}}(\mathcal{S},0) = \inf_{n \in \mathbb{N}} \inf_{L>0} r_{C-H^p_{L,\alpha}}(\mathcal{S},0,n). \)

In particular, (38) and (39) are true for \( C \in \{B,\text{LIN}\}. \)

**Proof.** Let us begin by proving (38). Fix \( \delta > 0 \) and choose \( n_0 \in \mathbb{N} \) such that

\[ r_{C-H^p_{L,\alpha}}(\mathcal{S},0) \leq \inf_{n \in \mathbb{N}} r_{C-H^p_{L,\alpha}}(\mathcal{S},0,n) + \delta. \]

Let \( r_{C-H^p_{L,\alpha}}(\mathcal{S},0,n_0) = \frac{k_0}{n_0} \), i.e. there exist functions \( f_0 : [0,1]^{n_0} \to [0,1]^{k_0} \) and \( g_0 : [0,1]^{k_0} \to [0,1]^{n_0} \) such that \( f_0 \in C, g_0 \in H^p_{L,\alpha} \) and

\[ \mu(\{ x \in \mathcal{S} : g_0 \circ f_0(x)_{n_0-1} \neq x_{n_0-1} \}) = 0 \]

for every \( \mu \in \mathcal{P}_\sigma(\mathcal{S}) \). As \( \text{id} \in C \), we can assume that \( k_0 \leq n_0 \).

Fix \( n \in \mathbb{N} \) and write it (uniquely) as \( n = \ell n_0 + m \), where \( \ell, m \in \mathbb{N}_0 \) and \( 0 \leq m < n_0 \). Define \( f : [0,1]^n \to [0,1]^{k_0+m} \) as the \( \ell \)-fold product of \( f_0 \) followed by the identity on the remaining \( m \) coordinates. More precisely, we set

\[
\begin{align*}
\mathbf{f}(x_0, x_1, \ldots, x_{n-1}) &= (f_0(x_0, \ldots, x_{n_0-1}), f_0(x_{n_0}, \ldots, x_{2n_0-1}), \ldots, f_0(x_{(\ell-1)n_0}, \ldots, x_{\ell n_0-1}), x_{\ell n_0}, \ldots, x_{\ell n_0+m-1}).
\end{align*}
\]

By the assumptions on \( C \), \( f \) belongs to \( C \). Similarly, we define \( g : [0,1]^{k_0+m} \to [0,1]^n \) as the \( \ell \)-fold concatenation of \( g_0 \) followed by the identity on the remaining \( m \) coordinates. More precisely, we set

\[
\begin{align*}
\mathbf{g}(x_0, x_1, \ldots, x_{k_0+m}) &= (g_0(x_0, \ldots, x_{k_0-1}), g_0(x_{k_0}, \ldots, x_{2k_0-1}), \ldots, g_0(x_{(\ell-1)k_0}, \ldots, x_{\ell k_0-1}), x_{\ell k_0}, \ldots, x_{\ell k_0+m-1}).
\end{align*}
\]

The shift-invariance of \( \mu \) together with (41) and definitions of \( f \) and \( g \) give

\[
\mu(\{ x \in \mathcal{S} : g \circ f(x)_{n_0-1} \neq x_{n_0-1} \}) = \mu(\{ x \in \mathcal{S} : \exists_{0 \leq j < \ell} g_0 \circ f_0(x)_{j n_0}^{(j+1)n_0-1} \neq x_{j n_0}^{(j+1)n_0-1} \}) = \\
\mu\left( \bigcup_{j=0}^{\ell-1} \sigma^{-j n_0}(\{ x \in \mathcal{S} : g_0 \circ f_0(x)_{n_0-1} \neq x_{n_0-1} \}) \right) = 0.
\]

Let us show now that for large \( n \), the map \( g \) belongs to \( H^p_{L+\varepsilon,\alpha} \), i.e. it is \((L+\varepsilon,\alpha)\)-Hölder in the norm \( \| \cdot \|_p \). Let us consider the case \( p \in [1, \infty) \), as the case \( p = \infty \) is straightforward. Fix \( x, y \in [0,1]^{k_0+m} \). We have the following series of inequalities (see below for explanations)
\[
\|g(x) - g(y)\|_p^p = \sum_{i=0}^{\ell-1} \|g_0(x)_{(i+1)k_0 - 1} - g_0(y)_{(i+1)k_0 - 1}\|_p^p + \sum_{i=0}^{m-1} |x_{i\ell k_0 + 1} - y_{i\ell k_0 + 1}|^p
\]

\[
\leq \ell^n \left( \frac{n_0}{\ell n_0 + m} \sum_{i=0}^{\ell-1} \|x_{(i+1)k_0 - 1} - y_{(i+1)k_0 - 1}\|_p^p + \sum_{i=0}^{m-1} |x_{i\ell k_0 + 1} - y_{i\ell k_0 + 1}|^p \right)
\]

\[
\leq \ell^n \left( \frac{n_0}{\ell n_0 + m} \sum_{i=0}^{\ell-1} \|x_{(i+1)k_0 - 1} - y_{(i+1)k_0 - 1}\|_p^p + \sum_{i=0}^{m-1} |x_{i\ell k_0 + 1} - y_{i\ell k_0 + 1}|^p \right)\alpha
\]

\[
= \ell^n \left( \frac{n_0}{\ell n_0 + m} \right)^\alpha \|x - y\|_p^{\alpha p}
\]

Equality (42) follows from the definition of the \( p \)-th norm (recall that it is normalized). Inequality (43) follows from \( g_0 \in \mathcal{H}_{L,\alpha}^p \), \( L \geq 1 \), \( \alpha \in (0, 1] \) and \( x, y \in [0, 1]^{\ell k_0 + m} \). Applying Jensen’s inequality (see e.g. [31, Theorem 3.3]) yields (44). As \( k_0 \leq n_0 \), inequality (45) follows. For (46) we use the definition of the \( p \)-th norm once more. If \( n \) is large enough, then \( L^n \left( 1 + \frac{n_0}{\ell k_0} \right)^\alpha \leq (L + \varepsilon)^p \) (since \( \ell \to \infty \) as \( n \to \infty \)). We have therefore found a compressor-decompressor pair consisting of \( f \in \mathcal{C} \) and \( g \in \mathcal{H}_{L,\varepsilon,\alpha}^p \), hence we can estimate (for \( n \) large enough)

\[
\rho_{\mathcal{C}, \mathcal{H}_{L,\varepsilon}^p}^n \left(S, 0, n \right) \leq \frac{\ell k_0 + m}{n} = \frac{\ell k_0 + m}{\ell n_0 + m} \leq \frac{k_0}{n_0} + \frac{n_0 - 1}{n} = \rho_{\mathcal{C}, \mathcal{H}_{L,\alpha}^p}^n \left(S, 0, n_0 \right) + \frac{n_0 - 1}{n}.
\]

Taking \( \limsup \) and applying (40), we obtain

\[
\limsup_{n \to \infty} \rho_{\mathcal{C}, \mathcal{H}_{L,\varepsilon}^p}^n \left(S, 0, n \right) \leq \rho_{\mathcal{C}, \mathcal{H}_{L,\alpha}^p}^n \left(S, 0, n_0 \right) \leq \inf_{n \in \mathbb{N}} \rho_{\mathcal{C}, \mathcal{H}_{L,\alpha}^p}^n \left(S, 0, n \right) + \delta.
\]

As \( \delta > 0 \) was arbitrary, (38) is proved. For (39) observe that the definition of \( \rho_{\mathcal{C}, \mathcal{H}_{L,\varepsilon,\alpha}^p}^n \left(S, 0 \right) \) and (38) imply that

\[
\inf_{n \in \mathbb{N}} \rho_{\mathcal{C}, \mathcal{H}_{L,\varepsilon,\alpha}^p}^n \left(S, 0 \right) \leq \rho_{\mathcal{C}, \mathcal{H}_{L,\varepsilon,\alpha}^p}^n \left(S, 0 \right) \leq \inf_{n \in \mathbb{N}} \rho_{\mathcal{C}, \mathcal{H}_{L,\alpha}^p}^n \left(S, 0 \right).
\]

Taking \( \inf \) on both sides yields (39), as the function \((0, \infty) \ni L \mapsto \inf_{n \in \mathbb{N}} \rho_{\mathcal{C}, \mathcal{H}_{L,\alpha}^p}^n \left(S, 0 \right) \) is non-increasing in \( L \).

**Appendix E. Examples - Calculations**

**E.A.** **Example IV.C.2.** Let

\[
S_m = \bigcup_{n \in \mathbb{Z}} \sigma^n(A_m) \text{ and } S := \bigcup_{m \geq 1} S_m,
\]

where

\[
A_m := \{(\ldots, 0, 0)\} \times [0, \frac{1}{2m}]^m \times \{(0, 0, \ldots)\} \subset [0, 1]^Z,
\]

with the cube \([0, \frac{1}{2m}]^m\) located on coordinates \(0, 1, \ldots, m - 1\). We shall prove

\[
\text{mdim}_M(S) = 0 \text{ and } \overline{\text{mdim}}_B(S) = 1.
\]
S is clearly $\sigma$-invariant. Let $\bar{\theta} = (\ldots, 0, 0, 0, \ldots) \in [0, 1]^\mathbb{Z}$. Note that each $S_m$ is compact (in the metric $\tau$) with
\[ \text{diam}(S_m) \leq \frac{2m}{2^m} \text{ and } \bar{\theta} \in S_m, \]
hence $S$ is compact. Moreover, for every $x \in S$ it holds $\sigma^n x \to \bar{\theta}$ as $n \to \infty$, hence $\mathcal{P}_\sigma(S) = \{\delta_{\bar{\theta}}\}$.

It follows from the Variational Principle (Theorem VII.B.1) that $\text{mdim}_f(S) = 0$. On the other hand, for every $m \geq 1$ it holds
\[ [0, \frac{1}{2^m}]^m \subset \pi_m(S), \]
hence $\overline{\text{dim}}_B(\pi_m(S)) \leq m$ and therefore $\overline{\text{mdim}}_B(S) = 1$.

**E.B. Example VI.A.1.** The goal of this subsection is to prove inequality (6). We will need the following lemma.

**Lemma E.1.** Fix $\delta \in (0, \frac{1}{2}]$, $n \in \mathbb{N}$ and $x \in \{0, 1\}^n$. Let $B(x, \delta)$ be the ball in the norm $\| \cdot \|_1$ on $\{0, 1\}^n$, i.e.
\[ B(x, \delta) = \{y \in \{0, 1\}^n : \|x - y\|_1 < \delta\}. \]
Then $\#B(x, \delta) \leq 2^{nH(\delta)}$, where $H(\delta) = -\delta \log \delta - (1 - \delta) \log(1 - \delta)$.

**Proof.** Fix $y \in B(x, \delta)$. Then
\[ \frac{1}{n} \sum_{i=0}^{n-1} |x_i - y_i| < \delta, \text{ where } x = (x_0, \ldots, x_{n-1}), y = (y_0, \ldots, y_{n-1}). \]
Therefore, the set $I_y = \{0 \leq i < n : x_i \neq y_i\}$ satisfies $I_y \leq \delta n$. Moreover, vector $y$ is uniquely determined by $I_y$, hence the assignment $B(x, \delta) \ni y \mapsto I_y \subset \{0, \ldots, n-1\}$ is injective. Consequently
\[ \#B(x, \delta) \leq \#\{I \subset \{0, \ldots, n-1\} : \#I \leq n\delta\} = \sum_{0 \leq i \leq n\delta} \binom{n}{i} \leq 2^{nH(\delta)}, \]
where the last inequality follows from [28, Lemma 3.6] (recall that we take logarithms in the base 2). \hfill \Box

Let $S := \{0, 1\}^\mathbb{Z}$. We will show that for any $\alpha \in (0, 1]$ and $L \geq 1$ it holds that
\[ \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_\sigma} r^{L_1}_{\text{H}, \alpha} (\mu, \varepsilon) \geq \frac{\alpha(1 - H(\frac{1}{2}))}{\log 8L} > 0. \tag{47} \]
As the quantity $r^{L_1}_{\text{H}, \alpha} (\mu, \varepsilon)$ is decreasing in $L$, this will be sufficient for proving (6) for all $L > 0$.

We will find a single measure for which the lower bound in (47) holds. Let $\mu = \otimes (\frac{1}{2} \delta_0 + \frac{1}{2} \delta_1) \in \mathcal{P}_\sigma(S)$. Fix $\varepsilon \in (0, \frac{1}{10})$. Fix $n \in \mathbb{N}$ and let $r^{L_1}_{\text{H}, \alpha} (\mu, \varepsilon, n) = \frac{k}{n}$ for some $k \in \mathbb{N}$. There exists then a Borel map $f : [0, 1]^n \to [0, 1]^k$ and $(L, \alpha)$-Hölder map $g : [0, 1]^k \to [0, 1]^n$ (in norm $\| \cdot \|_1$) such that
\[ \int_{[0, 1]^n} \|x - g \circ f(x)\|_1 \, d(\pi_n)_* \mu(x) \leq \varepsilon. \tag{48} \]
Clearly $(\pi_n)_* \mu = (\frac{1}{2} \delta_0 + \frac{1}{2} \delta_1) \otimes n$. Let $A_n \subset \{0, 1\}^n$ be defined as $A_n = \{x \in \{0, 1\}^n : \|x - g \circ f(x)\|_1 \leq 2\varepsilon\}$. By the Chebyshev inequality (see e.g. [55, (5.30)]) and (48) we have
\[ \#(\{0, 1\}^n \setminus A_n) \leq \frac{2^n}{2\varepsilon} \int_{\{0, 1\}^n \setminus A_n} \|x - g \circ f(x)\|_1 \, d(\pi_n)_* \mu(x) \leq 2^{n-1}. \]
Therefore
\[ \#A_n \geq 2^{n-1}. \tag{49} \]
Lemma E.1 (applied with $\delta = 8\varepsilon$) implies that there exists a subset $B_n \subset A_n$ satisfying
\[ \|x - y\|_1 \geq 8\varepsilon \text{ for every } x, y \in B_n \text{ such that } x \neq y. \tag{50} \]
and

\[ \#B_n \geq \frac{\#A_n}{2^nH(8\varepsilon)}. \]

By the triangle inequality, (50) and the definition of \( A_n \), for distinct \( x, y \in B_n \) we have
\[ \| g \circ f(x) - g \circ f(y) \|_1 \geq \| x - y \|_1 - \| x - g \circ f(x) \|_1 - \| y - g \circ f(y) \|_1 \geq 4\varepsilon. \]

and consequently, as \( g \) is \((L,\alpha)\)-Hölder in \( \| \cdot \|_1 \),
\[ 4\varepsilon \leq \| g \circ f(x) - g \circ f(y) \|_1 \leq L\| f(x) - f(y) \|_1^\alpha \] for \( x, y \in B_n, \ x \neq y \).

This implies that \( f \) is injective on \( B_n \), hence \( \#f(B_n) = \#B_n \). Moreover, by (52), elements of the set \( f(B_n) \) are \( \left( \frac{4\varepsilon}{L} \right)^\frac{1}{\alpha} \)-separated in the norm \( \| \cdot \|_1 \) on \([0,1]^k \), hence \( \#f(B_n) \leq \left( \frac{4\varepsilon}{L} \right)^{-\frac{k}{\alpha}} \) (as \( f(B_n) \) is \( \left( \frac{4\varepsilon}{L} \right)^\frac{1}{\alpha} \)-separated in the norm \( \| \cdot \|_\infty \) as well, since \( \| \cdot \|_\infty \geq \| \cdot \|_1 \)). Combining this with (49) and (51) gives bounds
\[ 2^{n(1-H(8\varepsilon)) - 1} \leq \#B_n = \#f(B_n) \leq \left( \frac{4\varepsilon}{L} \right)^{-\frac{k}{\alpha}}. \]

Taking logarithms we obtain
\[ n(1 - H(8\varepsilon)) - 1 \leq \frac{k}{\alpha} \log \frac{L}{4\varepsilon}, \]

therefore (recall that \( L \geq 1 \) and \( \varepsilon < \frac{1}{16} \), hence \( \frac{L}{4\varepsilon} > 1 \) and \( H(8\varepsilon) < 1 \))
\[ r_{B-H_{1,\alpha}}^1(\mu, \varepsilon, n) = \frac{k}{n} \geq \frac{\alpha(1 - H(8\varepsilon))}{\log \frac{L}{4\varepsilon}} - \frac{1}{n \log \frac{L}{4\varepsilon}}. \]

This implies
\[ r_{B-H_{1,\alpha}}^1(\mu, \varepsilon, n) = \limsup_{n \to \infty} r_{B-H_{1,\alpha}}^1(\mu, \varepsilon, n) \geq \frac{\alpha(1 - H(8\varepsilon))}{\log \frac{L}{4\varepsilon}}. \]

We finally obtain
\[ \sup_{\varepsilon > 0} r_{B-H_{1,\alpha}}^1(\mu, \varepsilon) \geq r_{B-H_{1,\alpha}}^1(\mu, \frac{1}{32}) \geq \frac{\alpha(1 - H(\frac{1}{2}))}{\log 8L}. \]

Taking supremum over \( \mu \in \mathcal{P}_n(S) \) gives (47).

E.C. Example VI.A.2. Let \( A = \{0\} \cup \{ \frac{1}{n} : n \in \mathbb{N} \} \) and \( S = A^\mathbb{Z} \). Then, according to Example IV.C.1,
\[ \overline{\dim}_M(S) = \overline{\dim}_B(S) = \dim_B(A) = \frac{1}{2}. \]

We will prove
\[ \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_n(S)} r_{B-H_{\alpha}}(\mu, \varepsilon) = 0 \text{ for every } \alpha \in (0, 1]. \]

To that end, fix \( \varepsilon > 0, n \in \mathbb{N} \) and \( \mu \in \mathcal{P}_n(S) \). Since \( (\pi_n)_*\mu \) is a discrete measure with countably many atoms, there exists a finite set \( B \subset [0,1]^n \) with \( (\pi_n)_*\mu(B) \geq 1 - \varepsilon \). Since \( B \) is finite, there exists a linear map \( F : \mathbb{R}^n \to \mathbb{R} \) such that \( F([0,1]^n) \subset [0,1] \) and \( F \) is injective on \( B \) (e.g. projection onto a suitable line - there is only finitely many directions such that projection onto them will fail to be injective on a given finite set). Let \( f : [0,1]^n \to [0,1] \) be given by \( f = F|[0,1]^n \). Let \( g : f(B) \to [0,1]^n \) be its inverse on \( f(B) \). Note that \( g \) is \( L \)-Lipschitz with respect to the norm \( \| \cdot \|_\infty \) for \( L = \left( \min \{ \| x - y \|_\infty : x, y \in f(B), x \neq y \} \right)^{-1} \). The function \( g \) can be extended to an \( L \)-Lipschitz map from \([0,1]\) to \([0,1]^n\) for some \( L > 0 \) (see Remark III.A.8). Now
\[ \mu(\{ x \in S : g \circ f \circ \pi_n(x) = \pi_n(x) \}) \geq (\pi_n)_*\mu(B) \geq 1 - \varepsilon, \]

hence \( r_{\text{lin-L}}^L(\mu, n, \varepsilon) \leq \frac{1}{n} \) and \( r_{\text{lin-L}}^L(\mu, \varepsilon) = 0 \). Consequently
\[ \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_n(S)} r_{B-H_{\alpha}}(\mu, \varepsilon) \leq \sup_{\varepsilon > 0} \sup_{\mu \in \mathcal{P}_n(S)} r_{\text{lin-L}}(\mu, \varepsilon) = 0. \]

Note that in the above calculation we cannot guarantee a uniform bound on \( L \) (with respect to \( n \)) as \( \left( \min \{ \| x - y \|_\infty : x, y \in f(B), x \neq y \} \right)^{-1} \) can be arbitrary large for \( n \to \infty \).
E.D. Example VI.B.1. Let \( S \subset [0,1]^\mathbb{Z} \) be the subshift from Example IV.C.3, i.e.
\[
S = \{x \in [0,1]^\mathbb{Z} : \forall j \in \mathbb{Z} \|x\|^j_{j+1} \leq K\}
\]
for \( N, K \in \mathbb{N} \), \( K \leq N \). We shall prove that for every \( p \in [1,\infty], \alpha \in (0,1] \) it holds
\[
\inf_{L > 0} \sup_{\mu \in \mathcal{P}_p(S)} \sup_{e > 0} \| r_{S-N_L,\alpha}(\mu, e) \| = \inf_{L > 0} \sup_{\mu \in \mathcal{P}_p(S)} \sup_{e > 0} \| r_{S-N_L,\alpha}(\mu, e) \| = \alpha K/N.
\]
Theorem V.A.1 and the calculation from Example IV.C.3 give
\[
\frac{\alpha K}{N} = \inf_{L > 0} \sup_{\mu \in \mathcal{P}_p(S)} \sup_{e > 0} \| r_{S-N_L,\alpha}(\mu, e) \|,
\]
hence it suffices to prove
\[
\inf_{L > 0} \| r_{S-N_L,\alpha}(\mu, e) \| \leq \frac{\alpha K}{N}.
\]
We will apply Lemma D.1 and Proposition IX.C.1. Fix \( \varepsilon > 0 \). Let \( \ell \in \mathbb{N} \) be such that \( \frac{\alpha}{\ell N} \leq \varepsilon \). Set \( d := \lceil \alpha \ell K \rceil + 1 \). Then \( \alpha < \frac{d}{\ell K} \), hence by Proposition IX.C.1 there exist \( \phi : [0,1]^\ell K \to [0,1]^d \), \( \psi : [0,1]^d \to [0,1]^{\ell K} \) such that \( \phi \in \mathcal{B} \), \( \psi \in \mathcal{H}_\alpha \) and \( \psi \circ \phi(x) = x \) for every \( x \in [0,1]^{\ell K} \). Define the set
\[
\mathcal{A} := \{A \subset [0,1,\ldots,\ell N - 1] : \#A = \ell K\}
\]
consisting of all subsets of \( \{0,\ldots,\ell N - 1\} \) of cardinality \( \ell K \). Let \( C : \pi_{\ell N}(S) \to \mathcal{A} \) be any Borel map such that \( \text{supp}(x) \subset C(x) \) holds for every \( x \in \pi_{\ell N}(S) \). Such map exists as \( \#\text{supp}(x) \leq \ell K \) for every \( x \in \pi_{\ell N}(S) \) (for vectors \( x \in \pi_{\ell N}(S) \) with \( \#\text{supp}(x) < \ell K \), one can set \( C(x) \) to be e.g. the union of \( \#\text{supp}(x) \) with \( \ell K - \#\text{supp}(x) \) first zero coordinates of \( x \). This is clearly a Borel map). Moreover, let \( s : \mathcal{A} \to [\frac{1}{2},1] \) be a map such that \( |s(A) - s(B)| \geq \frac{1}{\ell K} |A - B| \) for \( A \neq B \) (i.e. it assigns to sets \( A \in \mathcal{A} \) points from \( [\frac{1}{2},1] \) in a maximally separated fashion). We are now ready to define a compressor \( f : [0,1]^{\ell N \cdot 1} \to [0,1]^{d+1} \) and a decompressor \( g : [0,1]^{d+1} \to [0,1]^{\ell N} \), \( f \in \mathcal{B} \) and \( g \in \mathcal{H}_\alpha^{\ell N} \), \( \ell N \) large enough. The compressor \( f \) will assign to \( x \in \pi_{\ell N}(S) \) the image under \( \phi \) of \( x \) restricted to the set \( C(x) \) which contains the support of \( x \), together with a signature \( s(C(x)) \). Knowing \( s(C(x)) \) (and hence \( C(x) \) itself) will allow us to decode \( x \) uniquely by applying \( \psi \) and setting coordinates from the complement of \( C(x) \) to zero. The fact that \( \psi \) is \( \alpha \)-Hölder and \( s \) separates sets from \( \mathcal{A} \) will allow us to conclude that the decompressor is Hölder as well. Specifically let us define \( f : [0,1]^{\ell N} \to [0,1]^{d+1} \),
\[
f(x) = \begin{cases} 
0, & x \notin \pi_{\ell N}(S) \\
(\phi(x|_{C(x)}), s(C(x))), & x \in \pi_{\ell N}(S)
\end{cases}.
\]
Clearly \( f \) is Borel. Define \( g : ([0,1]^{\ell N}) \to [0,1]^{\ell N} \) as
\[
g(x_1, \ldots, x_d, x_{d+1}) = \begin{cases} 
0, & x_{d+1} = 0 \\
\psi(x_1, \ldots, x_d) \uparrow s^{-1}(x_{d+1}), & x_{d+1} \neq 0
\end{cases},
\]
where \( \psi(x_1, \ldots, x_d) \uparrow s^{-1}(x_{d+1}) \) denotes the vector in \([0,1]^{\ell N}\) obtained by putting the consecutive elements of the vector \( \psi(x_1, \ldots, x_d) \) (which has length \( \ell K \)) in the consecutive coordinates from the set \( s^{-1}(x_{d+1}) \in \mathcal{A} \) (of cardinality \( \ell K \)) as well and setting other coordinates to zero. Note that \( g \) is well defined on \( f([0,1]^{\ell N}) \) and \( g \circ f = \text{id} \) on \( \pi_{\ell N}(S) \). Let us show now that \( g \) is \( \alpha \)-Hölder on \( f([0,1]^{\ell N}) \). As \( \psi \in \mathcal{H}_\alpha \), there exists \( L > 0 \) such that \( \psi \) is \( (L,\alpha) \)-Hölder in the norm \( \| \cdot \| \) on \([0,1]^d \). Note that \( f([0,1]^{\ell N}) \subset [0,1]^d \times \{0,1,2,3,\ldots,1 - \frac{1}{2(\#A - 1)}\} \). Fix \( x = (x_1, \ldots, x_d, x_{d+1}), \ y = (y_1, \ldots, y_d, y_{d+1}) \in f([0,1]^{\ell N}) \). Assume first that \( x_{d+1} \neq y_{d+1} \). Then \( |x_{d+1} - y_{d+1}| \leq \frac{1}{2(\#A - 1)} \), hence \( \|x - y\|_p \geq M \), where \( M = \frac{1}{(d+1)^{\frac{1}{2(\#A - 1)}}} \) for \( p \in (1,\infty) \) and \( M := \frac{1}{2(\#A - 1)} \) for \( p = \infty \). Therefore
\[
\|g(x) - g(y)\|_p \leq 1 \leq \frac{1}{M} \|x - y\|_p \text{ if } x_{d+1} \neq y_{d+1}
\]
Assume now that \( x_{d+1} = y_{d+1} \). By \( (L,\alpha) \)-Hölder continuity of \( \psi \) on \([0,1]^d \), we have
Indeed, if \( x,y \) closed and, by (58), of full measure 

\[ \text{We claim that } F = f \] 

Therefore and consequently \( x \in \mathbb{X} \) and \( y \in \mathbb{Y} \). As both \( g \) and \( f \) are continuous, the set \( \{ x \in [0,1]^n : g \circ f(x) = x \} \) is closed and, by (58), of full measure. Therefore \( \{ x \in [0,1]^n : g \circ f(x) = x \} \) and consequently

\[ A \subset \{ x \in [0,1]^n : g \circ f(x) = x \}. \]

Therefore \( f \) is injective on \( A \). Let \( F: \mathbb{R}^n \to \mathbb{R}^n \) be the linear extension of \( f \) (it exists as \( f \in \text{LIN} \)). We claim that \( F \) is injective on a larger set 

\[ E = \left( (\mathbb{R}^K \times [0,1])^\ell \times \mathbb{R}^m \right) \cup \left( ([0,1]^K \times \mathbb{R})^\ell \times \mathbb{R}^m \right). \]

Indeed, if \( x,y \in E \) are such that \( F(x) = F(y) \), then there exists \( \nu \in \mathbb{R}^m \) and \( t > 0 \) such that \( t(x+y) \in A \), \( t(y+v) \in A \) and \( f(t(x+v)) = f(t(y+v)) \). Consequently \( t(x+v) = t(y+v) \), hence \( x = y \). As \( F \) is linear, its injectivity on \( E \) implies that 

\[ \ker(F) \cap (E - E) = \{0\} \]
We also have (\(\mathbb{R}^K \times \{0\}^{N-2K} \times \mathbb{R}^K\)) \(\ell \times \{0\}^m \subset E - E\) if \(2K \leq N\) and 
\[n \times \{0\}^m \subset E - E\] if \(2K > N\). Therefore (59) implies \(\dim(Ker(F)) \leq n - \min\{2\ell K, \ell N\}\) and consequently \(k \geq \dim(Im(F)) \geq \min\{2\ell K, \ell N\}\). This gives bound 
\[r_{\text{LIN}-\mathcal{H}_\alpha}^p(\mu, 0, n) \geq \min\{2\ell K, \ell N\} = \ell \min\{2\ell K, N\} \geq \ell \min\{2\ell K, N\} = \frac{\ell}{\ell + 1} \min\{\frac{2K}{N}, 1\}\].
Taking \(\limsup\) and recalling that \(l \to \infty\) as \(n \to \infty\), we obtain finally 
\[r_{\text{LIN}-\mathcal{H}_\alpha}^p(\mu, 0) \geq \min\{\frac{2K}{N}, 1\}\].

Equality \(\min\{\frac{2K}{N}, 1\}\) = \(\min\{2\text{mdim}_M(S), 1\}\) follows from the calculation in Example IV.C.3. This concludes the proof of (57). Note that the upper bound \(\frac{2}{\alpha}\text{mdim}_M(S)\) of Theorem V.B.1 approaches the above lower bound \(2\text{mdim}_M(S)\) as \(\alpha \to 0\), hence the constant \(\frac{2}{\alpha}\) in Theorem V.B.1 cannot be in general replaced by any smaller one.

**Appendix F.** Lower bound for \(r_{\mathcal{B}-\mathcal{H}_\alpha}(\mu, \varepsilon)\)

Following closely the proof of [2, Lemma 13] (see also [2, Equation (75)]) we have the following proposition:

**Proposition F.1.** Let \(S\) be a closed and shift-invariant subspace of \([0, 1]^Z\) and \(\mu \in \mathcal{P}_\sigma(S)\). Then for \(0 < \varepsilon < 1\) and \(\alpha \in (0, 1]\) the following holds:

\[\alpha R_B(\mu, \varepsilon) \leq r_{\mathcal{B}-\mathcal{H}_\alpha}(\mu, \varepsilon)\].

**Proof.** Fix \(n \in \mathbb{N}\) and let \(r_{\mathcal{B}-\mathcal{H}_\alpha}(\mu, \varepsilon, n) = \frac{k}{n}\). There exist \(f : [0, 1]^n \to [0, 1]^k\), \(g : [0, 1]^k \to [0, 1]^n\) such that \(f\) is Borel, \(g\) is \((L, \alpha)\)-Hölder and \(B = \{x \in S : g(x)^{\alpha-1} \neq x^{\alpha-1}\}\) satisfies \(\mu(B) \leq \varepsilon\). Take \(A = \pi_n(S \setminus B) \subset [0, 1]^n\). Then \(A = g(f(A)) \subset [0, 1]^k\) and \(\text{dim}_B(f(A)) \leq k\). Since \(g\) is \(\alpha\)-Hölder, we have by [36, Lemma 3.3.(iv)] that \(\text{dim}_B(A) = \frac{\text{dim}_B(g(f(A)))}{\alpha} \leq \frac{1}{\alpha} \text{dim}_B(f(A)) \leq \frac{k}{\alpha}\). We also have \(\mu(\pi_n^{-1}(A)) \geq \mu(S \setminus B) \geq 1 - \varepsilon\), hence \(R_B(\mu, \varepsilon) \leq \frac{1}{\alpha} \frac{k}{n} \leq \frac{1}{\alpha} r_{\mathcal{B}-\mathcal{H}_\alpha}(\mu, \varepsilon, n)\). Taking \(\limsup\) on the right side, we get the desired result.
