Abstract

A simple numerical solution for general relativity in the Newtonian weak field regime is provided – no tensor calculus is required. The topics under consideration are the deflection of photons and neutrinos by the Sun, the relativistic rotation of Mercury’s orbit plane, the Shapiro time delay, and the gravitational redshift – namely, the four Solar System tests of general relativity. To simplify the calculations, Euler integration is used. Hopefully, this numerical solution can be found to be an important tool, primarily due to this simplicity.
On simulating the four Solar System tests of general relativity using two-parameter post-Newtonian gravitation with Euler integration

Abstract

A simple numerical solution for general relativity in the Newtonian weak field regime is provided – no tensor calculus is required. The topics under consideration are the deflection of photons and neutrinos by the Sun, the relativistic rotation of Mercury’s orbit plane, the Shapiro time delay, and the gravitational redshift – namely, the four Solar System tests of general relativity. To simplify the calculations, Euler integration is used. Hopefully, this numerical solution can be found to be an important tool, primarily due to this simplicity.

1 Introduction

In this paper we will describe a numerical solution for the deflection of photons and neutrinos by the Sun, for the relativistic orbit of Mercury around the Sun, for the Shapiro time delay of photons, and for the gravitational redshift of photons.

No tensor calculus is involved – only high school Physics is required (e.g. Newtonian gravity, the shell theorem, and the use of 3-dimensional vectors).

It is also recommended that one has already read about special relativity [1,2], and thus kinematic time dilation. For instance, Einstein’s light clock thought experiment is helpful for understanding kinematic time dilation, where \( \vec{v} \) is the 3-dimensional velocity vector, the speed of light in vacuum is precisely \( c = 299792458 \), and \( d\tau/dt \) is the rate of time (e.g. light clock tick rate):

\[
\frac{d\tau}{dt} = \frac{\sqrt{c^2 - ||\vec{v}||^2}}{c} = \sqrt{1 - \frac{||\vec{v}||^2}{c^2}}.
\]

The faster one goes, the slower their rate of time – the faster one goes, the less the internal process occurs. See Fig. 1 for a diagram of the kinematic time dilation.

Note that this solution is only valid in the weak field, where the gradient of the gravitational time dilation practically vanishes, and Newton’s inverse square law holds true – where only space is curved. Because of its simplicity however, this numerical solution can serve as a stepping stone for further education on the subject – including tensor calculus.

2 On the Schwarzschild solution and the shell theorem

After one understands kinematic time dilation, it is not too far a stretch for them to un-
derstand gravitational time dilation – gravitation is the interruption of internal process by
some other process at some distance away.

In this paper we rely on the Schwarzschild solution, which means that the Sun is taken
to be spherically symmetric, stationary, static, and non-rotating [1,3–5]:

\[ R_{\mu\nu} - \frac{1}{2} R g_{\mu\nu} + \Lambda g_{\mu\nu} = \frac{8\pi G}{c^4} T_{\mu\nu}, \]  
(2)

\[ ds^2 = -\left(1 - \frac{R_s}{r}\right)c^2 dt^2 + \frac{dr^2}{\left(1 - \frac{R_s}{r}\right)} + r^2(d\theta^2 + \sin^2 \theta d\phi^2), \]  
(3)

where \( R_s \) is the Schwarzschild radius:

\[ R_s = \frac{2GM}{c^2}, \]  
(4)

and the Sun’s mass is \( M = 1.98847 \times 10^{30} \), and Newton’s constant is \( G = 6.6743 \times 10^{-11} \).

The gravitational time dilation is:

\[ \frac{d\tau}{dt} = \sqrt{1 - \frac{R_s}{r}}. \]  
(5)

The closer one gets, the slower their rate of time – the deeper one goes, the less the internal
process occurs.

In essence, the Schwarzschild solution is a relativistic version of the shell theorem. See
Fig. 2 for a visualization of the shell theorem.

Although hindsight is 20/20, if the Schwarzschild solution was non-existent it would not
be terribly difficult to guess the correct form of Eq. 5 through brute force trial and error – it
has something to do with radius and the speed of light as the escape velocity, raised to some
power, and we could judge its correctness via the predictions of the numerical solution.

3 On deflection

In the case of deflection of photons and neutrinos by the Sun, the timeslice that we used is:

\[ \delta_t = 1. \]  
(6)

The analytical solution for the deflection angle of photons or neutrinos that are just grazing
the Sun is:

\[ \delta_d = \frac{4GM}{c^2 r} \left( \frac{1}{\pi \times 180 \times 3600} \right) = 1.75 \]  
(7)

arc seconds, where \( r = 6.9634 \times 10^8 \) is the distance of closest approach (e.g. the Sun’s radius).
The numerically predicted amount is like 1.75 arc seconds, which is practically identical to
the amount given by the analytical solution. See Fig. 3 for a diagram of the deflection.
4 On precession

In the case of the precession of the perihelion of Mercury, do note that Euler integration automatically leads to a negative rotation of Mercury’s orbit plane, but given a small enough timeslice, this negative rotation becomes negligible. For instance, where \( \vec{v}_o \) denotes the orbiter’s velocity vector:

\[
\delta_t = \frac{c}{||\vec{v}_o||} \times 10^{-5}. \tag{8}
\]

The analytical solution for the precession of the perihelion of Mercury is:

\[
\delta_p = \frac{6 \pi GM}{c^2 (1 - e^2) a} \left( \frac{1}{\pi \times 180 \times 3600} \right) \left( \frac{365}{88} \times 100 \right) = 42.937 \tag{9}
\]

arc seconds per Earth century, where \( e = 0.2056 \) is the eccentricity and \( a = 5.7909 \times 10^{10} \) is the semi-major axis. The numerically predicted amount is like 43 arc seconds per Earth century, which is practically identical to the amount given by the analytical solution. See Fig. 4 for a diagram of the precession.

5 On Shapiro time delay

In the case of the Shapiro time delay, the timeslice that we used is:

\[
\delta_t = \frac{1}{c}. \tag{10}
\]

The analytical solution for the round-trip Shapiro time delay is:

\[
\delta_s = \frac{2GM}{c^3} \log \left( \frac{R_x + R_y}{R_x - R_y} \right) = 10^{-4} \tag{11}
\]

seconds, where

\[
R_x = ||(-1000 \times c, R_g, 0) - (0, 0, 0)|| \tag{12}
\]

is the distance from the sender to the Sun’s location at the origin, and

\[
R_y = ||(-1000 \times c, R_g, 0) - (0, R_g, 0)||. \tag{13}
\]

is the distance from the sender to the Sun’s surface, which is just grazed at the Sun’s radius of \( R_g = 6.9634 \times 10^8 \). We assume that the communication system is symmetric, and so the distance from the receiver to the Sun’s centre is also \( R_x \) and the distance from the receiver to the Sun’s grazed surface is also \( R_y \). This analytical solution also relies on the fact that \( R_x \) and \( R_y \) are likely to be much larger than \( R_g \). The numerically predicted amount is like \( 10^{-4} \) seconds, which is practically identical to the amount given by the analytical solution. Note that the analytical solution is only an approximation, and that the numerical solution is the ground truth. See Fig. 5 for a diagram of the symmetric communication system.
6 On gravitational redshift

In the case of the gravitational redshift, the timeslice that we used is:

\[ \delta t = 1. \] (14)

Since we know for sure from the previous section that space is contracted around a gravitating body, we know that gravitational redshift automatically occurs. In the case of the Sun, where \( \lambda_e = 1, \) \( r_e = 6.9634 \times 10^8 \) (e.g. the Sun’s radius), and \( r_i \) is practically infinite, it is found that \( \lambda_i \) is:

\[ \lambda_i = \lambda_e \frac{\sqrt{1 - \frac{R_s}{r_i}}}{\sqrt{1 - \frac{R_s}{r_e}}} = 1.00000212 \] (15)

metres. The numerically predicted amount is like 1.00000212 metres, which is practically identical to the amount given by the analytical solution. See Fig. 6 for a diagram of the gravitational redshift.

7 On integration using steps in time

From here on in, we shall use Euclidean 3-dimensional space, with Cartesian coordinates, because we will be dealing with (post-)Newtonian gravity.

Generally, in all cases, where \( \ell_s \) denotes the Sun’s location at the origin, \( \ell_o \) denotes the orbiter’s location, and \( \vec{d} \) denotes the direction vector that points from the orbiter toward the Sun:

\[ \vec{d} = \ell_s - \ell_o, \] (16)
\[ \hat{d} = \frac{\vec{d}}{||\vec{d}||}, \] (17)

the Newtonian acceleration vector is:

\[ \vec{g}_n = \frac{\hat{d}GM}{||d||^2}. \] (18)

One parameter is closely related to the kinematic time dilation:

\[ \alpha = 2 - \sqrt{1 - \frac{||\vec{v}_o||^2}{c^2}}. \] (19)

Another parameter is the gravitational time dilation:

\[ \beta = \sqrt{1 - \frac{R_s}{||d||}}. \] (20)

Finally, the semi-implicit Euler integration for velocity and then location is:

\[ \vec{v}_o(t + \delta t) = \vec{v}_o(t) + \delta t \alpha \vec{g}_n, \] (21)
\[ \ell_o(t + \delta t) = \ell_o(t) + \delta t \beta \vec{v}_o(t + \delta t). \] (22)
Note that Newtonian gravity is the result where α = β = 1.

See Fig. 7 for a diagram of the integration of velocity. See Fig. 8 for a diagram of the integration of location.

8 Review

1. Kinematic time dilation is introduced in Eq. 1.

2. The Einstein field equations for gravitation are given in Eq. 2, which are solved for by Schwarzschild’s line element in Eqs. 3 and 4. Gravitational time dilation is introduced in Eq. 5.

3. Where velocity is equal to the speed of light (or very close, like for neutrinos), we found that in Eq. 6 that a timeslice of 1 second is suitable.

4. We found that Eq. 7 and the numerical solution both predict the same amount (e.g. 1.75 arc seconds of deflection).

5. Where velocity is variable, we found that in Eq. 8 that a variable timeslice is suitable.

6. We found that Eq. 9 and the numerical solution both predict the same amount (e.g. 43 arc seconds per Earth century of rotation).

7. Where velocity is equal to the speed of light for the Shapiro time delay, we found that in Eq. 10 that a timeslice of 1/c seconds is suitable.

8. We found that Eqs. 11, 12 and 13 and the numerical solution both predict the same amount (e.g. 10^{-4} seconds of delay).

9. Where velocity is equal to the speed of light for the gravitational redshift, we found that in Eq. 14 that a timeslice of 1 second is suitable.

10. We found that Eq. 15 and the numerical solution both predict the same amount of redshift of the photons that escape the gravitational field (e.g. an increase in wavelength from 1.0 to 1.00000212 metres).

11. We found the direction vector and its unit length version in Eqs. 16 and 17.

12. We found the Newtonian acceleration in Eq. 18.

13. Eq. 19 goes to show that internal process is equal to a resistance to gravitation, and that the effects of gravity are stronger the faster one goes. It also goes to show that 2G is the fundamental constant, not G. To be honest, Eq. 19 was first guessed at, and only then did we judge its correctness and actual meaning via the predictions of the numerical solution.

14. Eq. 20 goes to show that internal process is overcome by gravitational time dilation, and that the effects of gravity are stronger the closer one gets to the gravitating body.
15. With regard to Mercury in particular, Eq. 21 goes to show that part of the relativistic precession is due to the kinematic time dilation (e.g. where \(1 \leq \alpha \leq 2\)). Mercury is gravitated more than it would be using Newtonian gravitation alone, for Newtonian gravity alone does not take velocity into account.

16. With regard to Mercury in particular, Eq. 22 goes to show that the planet dwells longer when it’s closer to the Sun (e.g. where \(0 \leq \beta < 1\)), causing the rest of the relativistic perihelion precession. Mercury is gravitated more than it would be using Newtonian gravitation alone, for Newtonian gravity alone does not take the contraction of space around the gravitating body into account.

17. In the end, we have simulated the deflection of photons and neutrinos by the Sun, the relativistic rotation of Mercury’s orbit plane, the Shapiro time delay, and the gravitational redshift. All numerical solutions predict the same values as the analytical solutions.

9 Conclusion

The numerical solution to Einstein’s field equations that is provided in this paper requires a mastery of only high school-level mathematics and software development. This allows the student to become gently acquainted with general relativity and numerical algorithms, before having to master the required tensor calculus.

The solution calculated the deflection of photons and neutrinos by the Sun, the relativistic orbit of Mercury, the Shapiro time delay, and the gravitational redshift. For instance, the solution calculated the deflection angle of 1.75 arc seconds. As well, the solution calculated a precession angle of 43 arc seconds per Earth century. Also, the solution calculated a Shapiro time delay of \(10^{-4}\) seconds. Finally, the solution calculated an increase in wavelength from 1.0 to 1.00000212 metres because of gravitational redshift. Thus, the solution correctly calculates all four Solar System tests of general relativity.

The C++ / OpenGL codes are available upon request.
