Abstract

Background: Patients with chronic urticaria (CU) often report an impaired quality of life (QoL). Although a positive effect of addressing spirituality in health care has been proved in several chronic diseases, its potential role in CU has received no attention. This study evaluated spirituality and QoL in CU subjects with different control levels. Methods: In a single-centre observational study, 100 CU subjects were investigated using Functional Assessment of Chronic Illness Therapy-Spiritual Well-Being (FACIT-Sp-12) scale, Chronic Urticaria Quality of life Questionnaire (CU-Q2oL) and Urticaria Control Test (UCT). Results: Of 100 subjects, 82 were female and 18 were male. It was observed that subjects with not controlled CU presented FACIT Sp-12 meaning/peace (p = 0.004) significantly lower, and CU-Q2oL (p <0.0001) significantly higher (worst QoL) than subjects with controlled CU. There was no difference in the FACIT Sp-12 faith (p = 0.43) between groups. There was moderate direct correlation between FACIT Sp-12 faith and FACIT Sp-12 meaning/peace (r = 0.483; p <0.0001; n = 100). There was a significant strong inverse correlation between the CU-Q2oL and the UCT (r = -0.762; p <0.0001; n = 100). No correlation was found between the FACIT Sp-12 faith and CU-Q2oL, neither with UCT. Conclusion: No study has ever investigated the role of spirituality in managing patients with urticaria. Our findings support the impact of poorly controlled urticaria in spiritual well-being and QoL. Therefore, clinicians should pay more attention to spirituality among CU patients. We suggest that urticaria guidelines should include specific recommendations on spirituality assessment.

Introduction:

Chronic urticaria (CU) is a skin disorder in which red, swollen, itchy, and sometimes painful hives (wheals), angioedema, or both, repeatedly occur for more than 6 weeks.² Prevalence is estimated up to 1% in the general population², with those aged between 30 and 50 years most affected, and females affected approximately twice as often as males.³⁴⁶ The current guidelines classify CU as spontaneous (chronic spontaneous urticaria [CSU], with no specified eliciting factor involved) or inducible (chronic inducible urticaria [CIndU], with a specific eliciting factor involved).¹ Patients may concurrently experience CSU and CIndU in approximately 20% of cases.⁴

Existing evidence indicates that symptoms of CU have a deleterious effect on the quality of life (QoL).²⁷⁹ It impacts daily activities and emotional well-being; some patients’ health status is comparable to that of coronary artery disease and severe asthma patients. It also causes inconvenience in family structures, compromising performance at work, school, and negatively impacting on leisure activities. It compromises patients’ QoL, mainly those with more severe disease or who are diagnosed with chronic spontaneous urticaria.⁷¹⁰ Until now there are no reliable biomarkers to identify and measure disease activity in CSU. Consequently, use of patient reported outcomes (PROs) is crucial when evaluating and monitoring different aspects of chronic urticaria such as disease activity/severity, disease control, and QoL. Five different PROs that measure various aspects of disease severity/activity and QoL are used routinely in research and clinical practice of chronic urticaria. Four of these PROs are urticaria-specific: weekly Urticaria Activity Score (UAS7); Urticaria Control
Test (UCT); and Chronic Urticaria Quality of Life Questionnaire (CU-Q2oL); two are angioedema-specific: Angioedema Activity Score (AAS) and Angioedema Quality of Life Questionnaire (AE-QoL). Numerous other factors also may influence QoL. Among those likely to be important is spiritual well-being (SpWB). Viewed as a multifaceted construct, SpWB usually refers to a sense of meaning or purpose in life, inner peace and harmony, and the strength and comfort drawn from faith. SpWB has been measured over two dimensions (Meaning/Peace and Faith). Recent studies suggest a broad protective relationship between religious participation and population health. Although a positive effect of addressing spirituality in health care has been proved in several chronic diseases, spiritual well-being in patients with CU has never received attention.

The aim of this study was to evaluate spirituality and QoL in CU subjects with different control levels (subjects with controlled CU and those with not controlled CU).

**Methods:**

**Patients**

We conducted a prospective single-centre observational study with 100 consecutive patients from the outpatient clinic of a Urticaria Center of Reference and Excellence (GA2 LEN UCARE, www.ga2len-ucare.com) at the Immunology Service of a university hospital. Patients were enrolled after informed consent was obtained. The study was submitted and approved by Comitê de Ética em Pesquisa do Hospital Universitário Clementino Fraga Filho (HUCFF-UFRJ), CAAE 45067715.5.0000.5257.

**Measures**

**Urticaria control assessment**

The UCT is a developed and validated instrument to determine the level of disease control in all forms of CU. It was originally developed in German and it has been validated to brazilian portuguese by our group. Two forms of the UCT are available: the long form UCT (UCTlg) (8 questions) and the short form UCT (UCTsh) (4 questions). Because the results of both UCT forms have been found to correlate extensively, the more convenient UCTsh is primarily used, both, in clinical trials and routine patient care. The categorizing recommendation is poorly controlled CU (UCT < 12) [n = 45] and well controlled CU (UCT ≥ 12).

**Spiritual Well-Being**

SpWB was measured using the Functional Assessment of Chronic Illness Therapy-Spiritual Well-Being (FACIT-Sp-12) Questionnaire. The FACIT-Sp-12 measures subjects’ overall spiritual well-being and includes 2 subscales: meaning/peace and faith. The total score was obtained by summing all individual items (range, 0–44, with higher scores indicating greater spiritual well-being), and the subscale scores were obtained by summing all items in each domain. The meaning/peace subscale measures sense of meaning, peace, and harmony, and purpose in life (range, 0–32). The faith subscale assesses the association between illness, faith, and spiritual beliefs as well as how one finds solace in one’s faith (range, 0–16).

**Quality of Life**

Quality of life was measured using the CU-Q2oL. The CU-Q2oL is a CSU-specific health-related QoL questionnaire consisting of 23 questions. The questions cover different aspects of CSU’s impact on patients’ lives including pruritus, swelling, daily life activities, sleep, appearance, and limitations. CU-Q2oL scores range from 23 to 115, with a higher score indicating stronger impairment of health-related QoL.

**Statistical Analysis**

First, to compare SpWB and QoL between the 2 groups (subjects with controlled CU and those with not controlled CU), univariate analyses were performed using a Mann-Whitney U test. Association between SpWB, QoL and disease control was assessed by Spearman’s rank correlation coefficient.
Nonparametric models were performed because the scores had a non-Gaussian distribution, according to the rejection of the hypothesis by the Shapiro-Wilk normality test. A $p$ value of $< 0.05$ was regarded as statistically significant. All statistical analyses were performed using SAS(r) System statistical software, version 6.11 (SAS Institute, Inc., Cary, North Carolina).

**Results:**

**Subject Characteristics**

Of 100 subjects, 82 were female and 18 were male (mean $\pm$ standard deviation [SD] age, 43 $\pm$ 15 years) [Table 1]. The characteristics of the subjects are summarized in Table 1.

**Score Characteristics**

Table 2 provides a description of the scores, in the total sample and by groups: poorly controlled CU [$n = 45$] and well controlled CU [$n = 55$].

The scores did not present a normal distribution (Gaussian), according to the Shapiro-Wilk normality test, at the level of 5%. Therefore, the most appropriate measures for summarizing the data were by quartiles (median, interquartile range [Q1 - Q3], minimum and maximum).

**FACIT-Sp-12 Meaning/Peace, FACIT-Sp-12 Faith and CU-Q2oL between controlled and not controlled subjects**

It was observed that subjects with not controlled CU presented FACIT Sp-12 meaning/peace ($p = 0.004$) significantly lower, and CU-Q2oL ($p < 0.0001$) significantly higher (worst QoL) than subjects with controlled CU. There was no difference in the FACIT Sp-12 faith ($p = 0.43$) between the groups.

**FACIT-Sp-12 Meaning/Peace, FACIT-Sp-12 Faith, CU-Q2oL and UCT correlation**

There was moderate direct correlation between FACIT Sp-12 faith and FACIT Sp-12 meaning/peace ($r = 0.483; p < 0.0001$).

Significant moderate inverse correlation was found between FACIT Sp-12 meaning/peace and CU-Q2oL ($r = -0.457; p < 0.0001$).

FACIT Sp-12 meaning/peace correlated weak with UCT ($r = 0.331; p = 0.0007$) [Figure 1].

No correlation was found between the FACIT Sp-12 faith with UCT ($r = 0.055; p = 0.58$) [Figure 2], neither with CU-Q2oL ($r = -0.113; p = 0.26$).

There was a significant strong inverse correlation between the CU-Q2oL and the UCT ($r = -0.762; p < 0.0001$) [Figure 3].

**Discussion:**

To the best of our knowledge, this is the first study to assess spiritual well-being in subjects with CU. We found that subjects with not controlled CU appeared to experience spiritual well-being on a level worst to that of those with controlled CU. Shenefelt & Shenefelt suggest that reactions to skin disorders have had and continue to have extensive spiritual aspects. They mention modern understandings of skin disorders and how to treat them have brought important advances, but in fact, healing of the skin continues to have a spiritual aspect and sometimes even today healing is hindered until the spiritual aspect is adequately addressed.22

Our study measured QoL and SpWB concurrently. We found that not controlled CU subjects present negatively associated with SpWB and QoL. This is in accordance with recent research which mostly demonstrated emotional distress affect CU and other skin disease patients QoL, leading them to have a low SpWB.9, 23-24 Therefore, providing spiritual care might improve QoL among such patients.
As well as Brady et al study on the evaluation of spirituality impact in quality of life of oncology patients we found that the faith subscale evidenced significantly smaller correlations with QoL than did the meaning/peace subscale. Meaning/Peace was the best predictor of QoL in the CU patients' evaluated.

In line with the UCT development study there was a strong correlation between UCT scores and CU-Q2oL. In this study we found that UCT scores didn't well correlate with FACIT-Sp-12 subscales, indicating that SpWB were not associated with CU patients' control status.

Current literature suggests several potential interventions intended to help individuals engage in positive spiritual coping. Life review has been suggested as a potential intervention. This intervention is targeted at helping individuals work through the meaning-making process to achieve a positive view of past and present life events.

The literature indicates some patient-generated suggestions for interventions. Regarding spiritually related needs, they suggested provider home visits, visits from volunteers, and that health care providers should generally offer a supporting attitude.

Conclusion:

Spirituality as marked by the meaning of self and inner independence cooperates with the affective states to determine the QoL of patients with CU. Considering patients’ spiritual concerns in the clinical setting is critical in enhancing QoL. No study has ever investigated the role of spirituality in managing patients with urticaria.

Our findings support the impact of poorly controlled urticaria in SpWB and QoL. For many patients, spiritual, existential, or religious beliefs can affect their understanding of illness and can influence treatment decisions. Therefore, clinicians should pay more attention to spirituality among CU patients. We suggest that urticaria guidelines should include specific recommendations on spirituality assessment.
